Abstract

This paper presents the structural equations for the first group of Euler method simulation models of changes in trade policy that are available for download on the USITC’s PE Modeling Portal at [https://www.usitc.gov/data/pe_modeling/index.htm](https://www.usitc.gov/data/pe_modeling/index.htm).

The models described in this paper are the result of ongoing professional research of USITC staff and are solely meant to represent the professional research of individual authors. These papers are not meant to represent in any way the views of the U.S. International Trade Commission or any of its individual Commissioners. Please address correspondence to david.riker@usitc.gov.
1 Basic Modeling Framework

The basic model focuses on a specific industry in a single national market. Products are differentiated by source country. There are three products sold in the market: domestic shipments (denoted $d$), imports that are subject to the trade policy change ($s$), and imports that are not subject to the policy change ($n$). The producer price of goods from source $j \in \{d, s, n\}$ is $p_j$, and the equilibrium quantity is $q_j$. The policy variable $\tau_s \geq 1$ is the tariff factor on the imports that are subject to the tariff change. It is equal to one plus the ad valorem tariff rate on these imports.

Consumers have nested constant elasticity of substitution (CES) preferences for the three products. The elasticity of substitution between the two types of imports ($\theta$) is greater than or equal to the elasticity of substitution between the domestic product and a CES composite of the imports ($\sigma$). Equation (1) is the CES price index for the two types of imports, and equation (2) is the total industry CES price index for the market.

\[
I = (b_s (p_s \tau_s)^{1-\theta} + b_n (p_n)^{1-\theta}) \frac{1}{1-\theta} 
\]

\[
P = ((p_d)^{1-\sigma} + (I)^{1-\sigma}) \frac{1}{1-\sigma} 
\]

$b_s$ and $b_n$ are calibrated parameters that capture preference symmetries and differences in the quality of the three products. The parameter $\eta < 0$ is the price elasticity of total demand in the industry. Equations (3), (4), and (5) are the demand functions for the three products.

\[
q_d = k (P)^{\eta} \left( \frac{P_d}{P} \right)^{-\sigma} 
\]

\[
q_s = k b_s (P)^{\eta} \left( \frac{I}{P} \right)^{-\sigma} \left( \frac{p_s \tau_s}{I} \right)^{-\theta} 
\]
\[ q_n = k \ b_n \ (P)^\eta \left( \frac{I}{P} \right)^{-\sigma} \left( \frac{P_n}{I} \right)^{-\theta} \]  \hspace{1cm} (5)

\( k \) is a demand parameter that is calibrated to the size of market.

Equations (6), (7), and (8) are the supply functions for the three products. They have constant price elasticities \( \epsilon_d \), \( \epsilon_s \), and \( \epsilon_n \).

\[ q_d = a_d \ (p_d)^{\epsilon_d} \]  \hspace{1cm} (6)

\[ q_s = a_s \ (p_s)^{\epsilon_s} \]  \hspace{1cm} (7)

\[ q_n = a_n \ (p_n)^{\epsilon_n} \]  \hspace{1cm} (8)

\( a_d \), \( a_s \), and \( a_n \) are calibrated supply parameters.

The market equilibrium is the set of prices for which the demand for each product is equal to its supply. These eight equations are used to simulate the change in equilibrium prices and quantities resulting from changes in tariff rates.

2 Variations on the Basic Model

There are several variations on the basic model that have been translated into a user-friendly spreadsheet format. All of the variations described in this paper assume perfect competition in the market, meaning that every producer in the industry is so small relative to the size of the whole market that the producer takes the market price as given and does not act strategically.\footnote{This is a common simplifying assumption in industry-specific models of changes in trade policy.}
2.1 Tariff Model with Non-Nested CES Demand and Three Sources of Supply

This is probably the most common industry-specific model used in trade policy analysis. This is the model described in (1) to (8). There are differentiated products from three distinct sources of supply. Non-nested CES demand means $\sigma = \theta$. The model simulates the effects of tariff changes on prices and quantities of imports and domestic shipments in a single national market.

2.2 Tariff Model with Nested CES Demand and Three Sources of Supply

This model permits the user to specify a higher elasticity of substitution between the two sources or types of imports. The equations of the model again correspond to (1) through (8), but $\sigma$ is not necessarily equal to $\theta$. This model also simulates the effects of tariff changes on prices and quantities of imports and domestic shipments in a single market.

2.3 Tariff Model with Non-Nested CES Demand and No Domestic Production

This model also includes two foreign sources of supply to the market, subject imports and non-subject imports, but in this case there is no domestic product. This is equivalent to the tariff model with non-nested CES demand with three sources of supply except that $q_d$ is equal to zero, or equivalently $a_d$ is equal to zero. Equations (9) through (13) describe this simpler model.

\[
P = \left( b_s \left( p_s \tau_s \right)^{1-\sigma} + b_n \left( p_n \right)^{1-\sigma} \right)^{-\frac{1}{1-\sigma}} \quad (9)
\]
\[ q_s = k \ (P)^\eta \left( \frac{P_s \tau_s}{P} \right)^{-\sigma} b_s \] (10)

\[ q_n = k \ (P)^\eta \left( \frac{P_n}{P} \right)^{-\sigma} b_n \] (11)

\[ q_s = a_s \ (p_s)^{\epsilon_s} \] (12)

\[ q_n = a_n \ (p_n)^{\epsilon_n} \] (13)

This model simulates the effects of tariff changes on prices and quantities of the two types of imports in the single national market. It assumes that there will continue to be no domestic product regardless of the tariff change.

2.4 Tariff Model with Non-Nested CES Demand and Two Distinct Markets

This model includes two source countries that are also destination markets, the domestic economy (d) and the foreign economy (f). Equations (14) through (19) describe this multi-region model.

\[ P_d = \left( (p_d)^{1-\sigma} + b_{fd} \ (p_f \ \tau_{fd})^{1-\sigma} \right)^{\frac{1}{\sigma-1}} \] (14)

\[ P_f = \left( b_{df} \ (p_d \ \tau_{df})^{1-\sigma} + (p_f)^{1-\sigma} \right)^{\frac{1}{1-\sigma}} \] (15)

\[ q_d = k_d \ (P_d)^{\eta_d} \left( \frac{p_d}{P_d} \right)^{-\sigma} + k_f \ (P_f)^{\eta_f} \left( \frac{p_f \ \tau_{df}}{P_f} \right)^{-\sigma} b_{df} \] (16)
\[ q_f = k_d \left( P_d \right)^{\eta_d} \left( \frac{p_f \tau_{fd}}{P_d} \right)^{-\sigma} b_{fd} + k_f \left( P_f \right)^{\eta_f} \left( \frac{p_f}{P_f} \right)^{-\sigma} \quad (17) \]

\[ q_d = a_d \left( p_d \right)^{\epsilon_d} \quad (18) \]

\[ q_f = a_f \left( p_f \right)^{\epsilon_f} \quad (19) \]

This model simulates the effects of tariff changes of either country, on prices and volumes of imports and domestic production in both of the markets \((d \text{ and } f)\).

### 2.5 Tariff Model with Non-Nested CES Demand and Intermediate Imports

This model includes two source countries, domestic \((d)\) and foreign \((f)\). An intermediate input is combined with value added to produce a final good. Country \(d\) imports both final and intermediate goods from country \(f\). Equations (20) through (25) describe this model.

Equation (20) is a price index for the upstream product, the intermediate inputs produced in countries \(d\) and \(f\). The elasticity of substitution is \(\theta\), and the asymmetry parameter is \(\gamma\).

\[ u = \left( (u_d)^{1-\theta} + \gamma (u_f \tau_{up})^{1-\theta} \right)^{\frac{1}{1-\theta}} \quad (20) \]

The price of the domestic product is a price index that combines the cost of the intermediates and value added with price \(w\). The elasticity of substitution is \(\lambda\), and the asymmetry parameter is \(\alpha\). \(\tau_{up}\) is equal to one plus the tariff rate on the imported intermediate good.

\[ p_d = \left( (w)^{1-\lambda} + \alpha (u)^{1-\lambda} \right)^{\frac{1}{1-\lambda}} \quad (21) \]
The model assumes that the supplies of these inputs are perfectly elastic, so $u_d$, $u_f$, and $w$ are exogenous variables in the model. Equation (22) is a price index for the downstream product, the final goods produced in countries $d$ and $f$. The elasticity of substitution is $\sigma$, and the asymmetry parameter is $\beta$.

$$P = \left( (p_d)^{1-\sigma} + \beta (p_f \tau_{down})^{1-\sigma} \right)^{\frac{1}{1-\sigma}}$$

(22)

$\tau_{down}$ is equal to one plus the tariff rate on the imported final good. Equations (23) and (24) are the demands for the domestic and imported final goods.

$$q_d = k \ (P)\eta \ (\frac{P_d}{P})^{-\sigma}$$

(23)

$$q_f = k \ (P)\eta \ (\frac{p_f \tau_{down}}{P})^{-\sigma} \ \beta$$

(24)

Finally, (25) is the derived demand for the imported intermediate input.

$$q_{int_f} = q_d \ p_d \ (\frac{u_f \tau_{up}}{u})^{1-\theta} \ \gamma$$

(25)

### 2.6 Binding Import Quota Model with Non-Nested CES Demand

This final model has the same structural equations as the basic model described in (1) through (6) and (8), except that (7) is replaced by the assumption that there is a perfectly inelastic supply of subject imports, $q_s$, that is determined by an exogenous binding import quota. Since this variation of the model focuses on binding quotas rather than tariffs, $\tau_s$ is set equal to one. The model simulates the effects of changes in the import quota on prices and quantities of imports and domestic shipments in the market.
