FOREWORD

This report was prepared by the U.S. International Trade Commission as a part of its investigation 332-65. That investigation was initiated in 1970 at the request of the President, who asked that the U.S. Tariff Commission study the conditions of competition between U.S. and foreign industries and report to him the results of the study. Several reports were completed under this investigation and were forwarded to the President during 1972-73. 1/

On May 9, 1972, the Council on International Economic Policy (CIEP) requested that the Commission continue its work under investigation 332-65 and provide reports on specific topics related to the contemplated negotiations on tariffs and non-tariff barriers under the General Agreement on Tariffs and Trade. The Commission prepared several additional reports in response to the CIEP request, including this report on the levels of industry protection in the United States and its major trading partners.

This report was prepared principally by Dr. Vernon O. Roningen of the Commission's Office of Economic Research.

1/ One of these reports was published as Competitiveness of U.S. Industries, TC Report 473, April 1972. Two other reports dealt with U.S. competitiveness with particular countries, and these reports were not subsequently published.

Introduction

This study attempts to outline, on an industry basis, the levels of protection in the United States and its major trading partners. Comparisons are made of nominal tariff protection across industries and across countries. Additionally, some measurements of "effective" tariff protection are made for comparative purposes on a cross-industry and cross-country basis. 1/ The study also includes some semi-quantitative measures of nontariff barriers for comparison with tariff rates. A statistical analysis of the relationship between protection levels, trade performance, and some industry characteristics concludes the study.

Those interested in comparisons of levels of nominal tariff protection can concentrate on the data and analysis presented in Part I. Part II deals with the measurement of "effective" tariff protection, or the total effects of the tariff structure on Value-Added (VA) in each industry. Part II also presents measurements and some analysis of this type of protection on a cross-industry and cross-country basis. Part III concentrates on traditional economic analysis; here an attempt is made to understand protection levels and the resulting trade patterns via the traditional method of testing economic hypotheses.

1/ "Effective" tariff rates are rates on value-added in production rather than on the product itself. Output product tariffs add to value-added by raising sales prices, while tariffs on input materials raise production costs and lower value-added.

Value-added in the study is defined to be total sales minus material services and inputs. This version of value-added (which includes service purchases) is used so that a particular type of model can be used in Part III.

All studies of this magnitude suffer from data inadequacies, category "matching" or concordance problems, and the difficulties of choosing adequate analytical techniques. As far as is possible, the study attempts to outline clearly the problems encountered and the known shortcomings in the data. Whenever clear alternative methods and measurements are possible, tractable alternatives are presented. Judgments are outlined and readers are given as much of the data and analysis as possible so that they can form alternative judgments if they wish.

The information needed about protection and the questions to be answered are quite simple. For example: What are the levels and/or incidence of tariff and nontariff protection among industries in the United States and its major trading partners? How did protection change for sectors of the U.S. economy during the Kennedy round tariff reduction period and how have these changes affected production and trade patterns? Where does the United States have its natural comparative advantage (so that tariff negotiators may know where to bargain the hardest for concessions from trading partners of the U.S.)? Where does the United States have the least comparative advantage (so that adjustment assistance may be readily offered if concessions are granted)? What are the costs of protection to the U.S. economy as a whole and what possible effects might general tariff reductions have in helping to dampen inflation? The answers to some of these questions lie partially in the careful preparation and presentation of economic data. The answers to the more difficult questions lie in the use of the data in intelligent economic analysis. This study tries to provide guidance along these lines.

Major Conclusions of the Study

The principal contribution of Part I lies in its presentation and comparison of several measures of nominal tariffs and a quasi-quantitative index of the incidence of Non-Tariff Barriers (NTB's) for both the United States and other countries. The study finds that general tariff patterns between the United States and its major trading partners are moderately correlated, with the rank nominal tariff pattern of the United States most similar to Canada's and least similar to Japan's. The same generalization holds true for NTB patterns, but with greater variability. The relationship between the U.S. tariff pattern and the average foreign tariff pattern is stronger than the relation of the U.S. pattern to individual country patterns. For each country studied, there is only a very weak relationship between its own tariff patterns and the pattern of incidence of its NTB's. Considering the implications of all the data in a body, the major trading countries' tariff patterns appear as moderately similar--as do their profiles of NTB incidence--but countries' own tariff and NTB patterns do not evidence much similarity.

Part II presents effective tariff (ET) rates for the United States and other countries, based on input-output relationships prevailing in the U.S. economy. Nominal and effective tariff rates are correlated quite closely on a ranking basis, indicating that the use of the nominal rate as a proxy for the ET rate is reasonable in a statistical analysis or in rank comparisons of tariff heights. Across countries, the rank

correlations show that if certain relationships hold between various sets of nominal rates, they will hold to a slightly lesser extent between the effective rates. For example, U.S. and foreign nominal tariff averages rank correlate at around 0.63, while U.S. and foreign effective tariff averages rank correlate at about 0.53. Generally, the overall variation in ET rates is much greater than that of nominal rates as among industries. Summary statistics indicate that the coefficient of variation for ET rates is well over twice that of nominal rates.

Comparing summary figures on overall nominal and effective tariff averages, it would appear that the cost of protection in the United States is a loss in real income of about five percent--down from 8 or 9 percent in 1965 but still more than half the 1965 cost. Considering that these costs do not include those of NTB's, further tariff negotiations can indeed play a role in increasing national welfare. However, it also is evident that if tariffs were eliminated the adjustment costs (through diminishing factor returns in certain sectors) probably would be as great as those following from the Kennedy Round reductions. The price effects of tariff elimination (i.e. any contribution to an anti-inflation effort), on the other hand, probably would be minimal.

Part III presents strong theoretical reasons for including the effective tariff rate in the measure of industries' comparative advantage in trade. There is also empirical evidence that encourages the supplementing of ET rates with measures of industries' relative health or comparative efficiency. A measure combining both of these aspects is proposed in this study and given preliminary estimates.

The study implies that foreign tariff reductions should be sought for sectors whose comparative advantage measures are high and which exhibit exporting characteristics, namely technology or professionalism and relative capital intensity. Protection can be safely bargained away for industries with a relatively high comparative efficiency or good general health. Adjustment assistance should be anticipated in industries which have low comparative advantage and are experiencing stiff import competition. These generally will be high tariff, low wage industries with low capital/labor ratios and few professionals in the work force.

Finally, trade performance and protection do not weigh heavily in the explanation of the existing status quo of industries. Therefore, the probable effects of reducing protection should be considered in the context of sector price and output behavior. Because trade does not drive the United States economy as much as it does the economies of other countries, the trade effects of protection changes should be fit into a framework that explains industrial performance reasonably well.

Trade negotiators may want some information at a more disaggregated product level than is provided in this study. Disaggregation below the level of the SIC means that researchers cannot tie into the wealth of data available from the Census of Manufactures and other sources. One may not be able to obtain data from existing sources to measure comparative advantage as defined in this part. However, one could crudely

approximate effective rates at the product level where the tariff rates exist. This could be done by using more aggregate input structures and tariffs and changing only the output tariff level in the ET formula.

It is important to note that when an industry as defined in this study produces many products, some of these products are competitive while others are not. The average industry comparative advantage is an average of all of its product performances. Hence it is important, even in a generally non-competitive industry, to identify the competitiveness of the various products. Removal of tariffs or NTB's, even in generally non-competitive industries, may affect only some of the product lines. Other products will be able to compete and should be so identified in the consideration of adjustment assistance.

PART I

Nominal Protection in the United States and Its Major Trading Partners

The measurement of tariff protection levels in the form of tariff averages and of Non-Tariff Barriers (NTB's) is a difficult problem. NTB's defy simple measurement, whether in comparisons across products, in comparisons across industries and countries, or in comparisons with tariff levels. 1/ Tariff level measures themselves depend heavily on aggregation and concordance problems. These problems arise because tariff and trade data are not always available for all countries on the same classification basis. Hence, concordances must be used to move data to a comparable basis. If data and analysis are needed on an industry level, these problems are further complicated because trade and tariff data are generally compiled on a more detailed product basis, while industry production and employment data are available only on a more aggregate production process or enterprise basis. In this study the desire for certain types of analysis meant that all data had to be aggregated to various versions of the industry-based Standard Industrial Classification (SIC) scheme. 2/

1/ An attempt has been made to document tariff and non-tariff barriers at the U.S. Tariff Commission. This study used data on tariff levels compiled by the General Agreement on Tariffs and Trade (GATT) and data on non-tariff barriers compiled and organized from several sources. See: Parts I, II, III, and IV of Trade Barriers, Report to the United States Senate and its Subcommittee on International Trade. U.S. Tariff Commission publication 665, Washington, D.C., April 1974.

2/ Definitions of the pure SIC (four digit) numbers used in this study can be found in: Standard Industrial Classification Manual 1967, Bureau of the Budget, Office of Statistical Standards, Washington, D.C. The SIC code tries to classify industry data by types of production activities. This gives rise to obvious problems with product oriented classifications because essentially the same product can sometimes be produced by different processes.

Aggregation from one classification scheme for trade and tariff data to another (so that the trade and tariff data can match industry data) calls for complex concordances. Two guiding and sometimes conflicting principles led to data presentation in this study by two separate concordance schemes. The first principle was the dedication to a thorough study of protection via the "effective" tariff concept as pursued in Parts II and III of this study. This led to presentation of most of the data by an Input-Output based SIC (IO-SIC), which is the scheme of classification of the 1963 U.S. input-output table. 1/ The second principle was to provide the most detailed level of disaggregation possible and still be confident of reasonable matches of trade and production data given the concordances available for this purpose. 2/ This latter consideration led to the laborious preparation of the Trade Commission SIC (TC-SIC) which tried to provide the least possible aggregation of pure four-digit numbers that would allow matching of trade and industry data. Where data are presented by either scheme, the table

---

1/ The definition of the input-output SIC and its relation to the pure SIC is found in a mimeographed tape description accompanying the large 478 sector 1963 input-output table on magnetic computer tape. This may be obtained from: The Interindustry Economics Division, Bureau of Economic Analysis, Department of Commerce, Wash., D.C. For most of the manufacturing sectors, IO-SIC numbers are identical to pure SIC numbers. However, the input-output table does aggregate some manufacturing industries and any of the mining and agriculture sectors. Stubs of the tables containing data on an IO-SIC basis bill also contain the pure SIC numbers so that the reader may see exactly what industries are aggregated in the manufacturing sectors.

2/ The basic available concordances for matching trade, tariff and production data are found in a Commerce Department publication, U.S. Foreign Trade Statistics, Classifications and Cross Classifications 1970, U.S. Department of Commerce, Bureau of the Census, Wash., D.C., 20233, February 1971. Most of the Trade Commission concordance work done for this study began with computer tapes of the concordances in this publication.

stub will show the four-digit pure SIC's that were combined. While this study will rely most heavily on the IO-SIC because of its emphasis on an inter-industry analytical approach, it will present some tariff data and analysis by the TC-SIC where feasible. 1/ As is always true in economic analysis, organization of the data depends heavily on the analytical approach used. Aside from analytical gains which are to be made with each kind of concordance, hopefully the multiple presentation will alert the reader to the seriousness of the concordance problem.

Aside from concordance problems, there are also problems of aggregation. It is generally well known that tariff averages differ considerably depending upon how tariff rates are weighted when they are aggregated. It is also recognized that no weighting scheme is perfect since each type of weight may introduce its own types of bias into the average. Therefore, wherever possible, various types of aggregate measures are shown for comparison purposes. This will give the reader an overall feeling for the aggregation weighting problem, and he can pinpoint those sectors whose averages are the most sensitive to the weighting scheme involved. It is generally true that for both the concordance and aggregation problems, some sectors' averages are very sensitive to schemes used while other sectors' averages are not. These differing sector

1/ The IO-SIC has the disadvantage of over-aggregation for some manufacturing sectors and under-aggregation for others. In the latter case it was not possible to accurately match trade data to TC-SIC sectors for all traded products. However, it was possible to find reasonable tariff rates for all sectors. From the inter-industry analytical viewpoint, the TC-SIC does not cover all of the sectors in the 1963 input-output table and thus is unacceptable.

sensitivities must be kept in mind by the reader making cross-sector comparisons of protection levels and by the researcher using the various data in statistical analysis.

As much of the data as possible are presented in tabular form. Key variables for comparison also are presented in graphical form for quick visual comparison. Many of the tables are in related formats. Due to the mass of the data to be presented -- and the consequent large volume of tabular and graphic materials -- all tables and charts are presented at the end of Part I, following page 21 .

Matching Trade, Tariff, and Production Data

In calculating tariff averages for the IO-SIC sectors, basic data on imports for consumption and Ad Valorem Equivalent (AVE) tariff rates for each TSUSA (Tariff Schedules of the United States Annotated) number were taken from Trade Commission computer tapes. They were combined in one tape, together with Post Kennedy Round (PKR) rates and concordance information relating the TSUSA to the "import based" SIC and the U.S. version of the Standard International Trade Classification (SITC). 1/ The final data tape had data on imports for consumption for 1965 and 1970. Data for 1970 were the most recent available when this study was initiated, and 1965 was the earliest year chosen because it minimized the extent of change in the TSUSA numbers. When the tape had been prepared, it was necessary to carry out several adjustments in order to find tariff

1/ The SITC is an official international 5-digit reporting system for trade data. It is used by most countries and by international agencies when publishing comparative trade data. The United States bases its own Schedule A import reporting codes and its Schedule B export reporting codes on the SITC. The U.S. version of the SITC refers to numbers used by the United States to report its trade data to the United Nations. These numbers differ slightly from the pure SITC in that some are not found in the official SITC and some have less than 5-digits. These exceptions are made when the United States feels that it own trade data reporting systems do not make the clear distinctions that are intended in the pure SITC.

The "import based" SIC is the version of the SIC matched to Schedule A numbers. This version is used for aggregation of U.S. import data to an SIC basis. A similar "export based" SIC is matched to Schedule B numbers for aggregating U.S. export data to an SIC base. Unfortunately, the "import based" and "export based" SIC numbers differ in some cases from the pure SIC. This occurs because product-grouped trade data do not always distinguish between similar products coming from different production sectors or processes.

Both product oriented and production activity oriented classification schemes have their own additions such as leftover categories for products or processes that can't be classified elsewhere.

rates for all IO-SIC sectors. This was done by splitting certain TSUSA numbers so that a tariff rate and some imports would be put into the IO-SIC categories that had none. The splitting procedure was somewhat arbitrary. This means that the tariff rates would be satisfactory but the corresponding import data might not be realistic for some sectors. Fortunately, very few sectors required this procedure. 1/

Finally, broad conversion factors were used to convert import data from an f.o.b. basis to a c.i.f. basis. This would make import figures a little higher and economically meaningful tariff averages a little lower. 2/

The source of data for foreign tariffs was a databank used in a previous Trade Commission study. 3/ These data were derived from a study done by the General Agreement on Tariffs and Trade (GATT) which put together, from national tariff schedules and data, a set of tariff averages for the 4-digit Brussels Tariff Nomenclature (BTN) scheme. Most major trading countries use this BTN system for their tariff schedules (the United States and Canada are two major exceptions). Thus, for a

---

1/ The advantage of the TC-SIC concordance is that when trade data could not be knowledgeably assigned to two or more pure SIC categories, those SIC categories were combined. The TC-SIC is a modification of the U.S. import based and the U.S. export based SIC. The IO-SIC is a modification only of the U.S. import based SIC.

2/ There were only 20 conversion factors. These were obtained from the September 1967 issue of report FT990 which reports U.S. imports. Let: M=imports, T=tariff rate, R=tariff revenue, and C=a c.i.f. to f.o.b. conversion factor. Then $R=T(f.o.b.)xM(f.o.b.)=T(c.i.f.)xM(c.i.f.)$ where $M(c.i.f.)=M(f.o.b.)x(1+c)$. Thus $T(c.i.f.)=T(f.o.b.)xM(f.o.b.)/M(c.i.f.)=T(f.o.b.)/(1+c)$.

3/ Trade Barriers, etc., op. cit.

meaningful comparison of U.S. and foreign protection levels, the GATT sources were relied upon since they have carried out a conversion of all tariffs to a common scheme.

The first step in the use of these data was the addition of a letter after some of the 4-digit BTN numbers. This allows a one-to-one correspondence of this new "5 digit" BTN with the SITC scheme. 1/ A concordance was then created between the pure SITC and the U.S. import based SITC. This allowed an indirect moving of GATT 4-digit BTN tariff rates to 5-digit BTN (the same 4-digit rate was applied to each 5-digit number), then to pure SITC, then to U.S. import SITC, and finally via data on the U.S. trade and tariff tape, to IO-SIC. There are possible sources of error in such a scheme. First, conversion by the GATT of U.S. and Canadian tariffs to BTN could have encountered problems. Second, the application of the same 4-digit rate to 5-digit BTN numbers suppressed any real variance in tariff rates that those 5-digit numbers might have had. The conversion of pure SITC to U.S. import-based SITC involves the same problem since the former scheme has a few more distinct numbers than the latter. Finally, the conversion from U.S. import-based SITC to IO-SIC has the problems inherent in that concordance.

Data on NTB's also came from a data file previously prepared for a Trade Commission study. 2/ It was compiled originally on a 5-digit

---

1/ For a listing of the BTN (5-digit) - 5-digit SITC concordance see: Nomenclature for the Classification of Goods in Customs Tariffs, Customs Co-operation Council, 40, Rue Washington, B-1050, Brussels, Belgium, 1972.

2/ Trade Barriers, etc. op. cit.

BTN basis and was aggregated to the IO-SIC level according to the scheme described above.

As mentioned previously, tariff averages vary depending upon the weighting scheme used for aggregation. In the case of U.S. tariffs directly from U.S. sources, the study used import weighted and unweighted averages. (The import weights were 1970 imports.) 1/ Import weighted averages have the disadvantage of possibly understating the effects of high prohibitive tariffs which may cause low or zero import weights. Unweighted averages have the problem that they may count tariff rates of items that do not significantly enter trade on an equal basis with items which are heavily traded. It has been proposed that some of these difficulties might be overcome by using domestic production weights or world trade weights. However, neither was operationally available at the TSUSA level for use in this study. Thus, only import weighted and simple averages are presented for U.S. tariffs aggregated from U.S. sources. 2/ The GATT provided two tariff averages at the BTN level for its data set. One was an own-country import weighted average and the other was a simple average of line items in the countries' tariff schedules. This study takes these two starting 4-digit BTN averages and averages the results down to IO-SIC levels. Data on non-tariff

1/ The use of 1970 imports to aggregate 1965 tariff rates added some advantages and some losses. It was an advantage to use constant weights for the 1965, 1970, and PKR rates so that one could minimize problems of tariff averages shifting due to changing weights. However, because of changes in TSUSA numbers some 1965 tariff rates were omitted in the averaging process. Hence, some 1965 rates seem to be out of line with the 1970 averages.

2/ In formulating the U.S. averages it was not possible to get away from import weighted averages at the TSUSA line item level since this method had to be used to convert many specific rates to ad valorem rates. The GATT would also have had to use some sort of import weights for this kind of conversion.

barriers were also averaged down to the IO-SIC level.

Data for the TC-SIC had the advantage of using direct concordances, which were prepared by the Trade Commission. Thus, U.S. simple tariff averages went directly from TSUSA to TC-SIC, while BTN tariffs went to SITC as outlined above and then directly to TC-SIC via a concordance. NTB measures went almost the same direct route used by the BTN-based tariffs. The TC-SIC also had the advantage of being able to convert U.S. trade directly from Schedules A and B to TC-SIC and international trade data directly from pure SITC to TC-SIC via modified official concordances.

International trade data for the IO-SIC went the same indirect route from pure SITC to IO-SIC as did the NTB data. U.S. import data went to the IO-SIC via the TSUSA TC-SIC concordance, and some export data went from the Schedule B export-based SIC to the IO-SIC.

Problems arise in the use of any concordance; the IO-SIC probably gives rise to more problems than the TC-SIC. However, the use of the data partly determines how serious the problems will be. If the objective is to correctly match trade and production data to get ratios such as imports to consumption or exports to shipments, correct and accurate concordances are essential. If the intention is to look at ratios of trade or tariff variables that have both been converted through the same imperfect concordance, then concordance errors may well cancel out, thus allowing an imperfect concordance to give meaningful ratios. For that reason, many researchers use variables such as export shares and trade

balances rather than variables that purport to be direct matches between trade and domestic production data. If variables such as import consumption ratios are used in a statistical analysis, rather than for observations of exact values, concordance defects may not greatly affect the statistical results. It is in these latter uses that this study applies concordances which might be deemed inadequate for other uses.

Comments on data procedures can be concluded with a description of the basic NTB data. The Trade Commission study made use of a databank that contained information on NTB's for several countries by product category. For each country, a matrix was created for 15 types of quantitative restrictions over 1,318 5-digit BTN numbers. The types of quantitative restrictions were: 1/

1. Bilateral quota
2. Global quota
3. Quota (unspecified)
4. Prohibited imports (embargoes)
5. State trading
6. Automatic licensing
7. Liberal licensing
8. Discretionary licensing
9. Licensing (unspecified)
10. Minimum price system
11. Seasonal restriction
12. Restriction (unspecified)
13. Export restraint
14. Suspended import restriction
15. Mixing regulation

A number "2" was placed in a cell (a particular restriction and a particular 5-digit BTN number) if the restriction applied to the entire BTN

1/ Page 162, Vol. 4, Trade Barriers, op. cit.

number and "1" was placed there if the restriction applied to only some of the items in the BTN category. The Trade Commission report on NTB's used this type of information to create various aggregate frequency indices by broad BTN categories. This study starts with the same data and makes approximately the same type of calculation. The NTB matrix is run through the concordance, adding across restrictions and then dividing by the total number of possible restrictions in a particular SIC category (this total will be 2 times 15 restrictions times the number of BTN numbers finally ending up in a particular SIC category via the concordance). The index in a particular SIC category is then the actual number of NTB's as a percentage of the total number possible within the SIC category. Thus, the NTB indices serve as relative measures of the frequency of existence of known NTB's within various SIC categories. At a minimum, the numbers can be treated as dummy variables indicating whether or not a particular SIC category probably has some NTB's applied to it. 1/ To the extent that more types of restrictions against a product are associated with quantitatively stronger restrictions against the product, the NTB indices may have some quantitative dimension to them.

The data and analysis

The data in Tables 1 and 3 give information on levels of nominal tariff protection and on relative frequencies of NTB's for the United States and her major trading partners. Chart 1 (following Table 1) gives

1/ "Probably" is used because it may be possible, because of concordance problems, to have NTB's assigned to SIC sectors where they do not belong. This could happen because the concordance may apply the same BTN number carrying an NTB to more than one SIC sector.

tariff profiles for the United States using the PKR rates in column 4 of Table 1.

A glance at differences in the U.S. PKR tariff rates and the GATT U.S. (PKR) rates indicates that concordance and weighting problems do exist for many sectors. Caution is required when examining sectors whose US-sourced and GATT-sourced tariffs differ significantly. The U.S. rates from U.S. data probably are more nearly correct as a comparative sector by sector measure of tariff rates. However, the GATT data would be more appropriate in comparing relative U.S. and foreign rates. Table 2 and Table 4 give rank correlation matrices, ranks, and summary statistics for Table 1 and Table 2, respectively. In spite of the concordance problem, the rank correlation between the U.S. PKR (column 4) and the GATT U.S. PKR (column 5) is about 0.8 in both Tables 1 and 3. Thus, on an overall ranking basis the two measures do not differ much from each other.

Table 5 sheds some light on the weighting problem. It gives rank correlation coefficients between weighted and unweighted versions of both U.S. tariffs and GATT tariffs. The weighted and unweighted rates for U.S. tariffs rank correlate around 0.85, while the GATT rates range from 0.86 to 0.94. 1/ Although the differences in ranks are not large, the weighting problem (given a particular concordance) causes almost as much difference in the rankings as when rates are converted to SIC with the same weighting scheme but using a different concordance.

1/ One expects the GATT rates to be more highly correlated since weighting differences occur only in going from country tariff schedules to the BTN. Simple averaging was used from the BTN to the IO-SIC for the GATT rates for both tables 1 and 3.

There are two measures of the average tariffs and NTB frequency indices of U.S. trading partners. Columns 9 and 16 of Tables 1 and 3 are simple averages of the measures for the EEC, Canada, Japan, and the United Kingdom. Columns 10 and 17 are weighted averages of the measures of 16 countries where the weights are shares of overall U.S. exports to these countries. 1/ The rank correlation coefficients between these measures are about 0.95 both for tariffs and NTB's. Hence, either of them can serve as a good proxy for restrictions facing the United States.

The general tariff patterns between the United States and its major trading partners are moderately correlated. The rank nominal tariff pattern of the United States seems to be the most similar to Canada's and the least similar to Japan's. The same generalization holds true for NTB patterns, except that there is more variability inasmuch as the correlation coefficients between U.S. and foreign patterns range between 0.18 and 0.61. Again, the U.S. is most similar to Canada and least similar to Japan. 2/

Chart 2 gives a graphical summary of differences between U.S. and foreign tariffs. The graph presents the simple differences between the U.S. rates in column 5 and the "average" foreign rate in column 10 of Table 3.

The relation between the U.S. tariff pattern and the average foreign tariff pattern is stronger than the relationships of the U.S. pattern

---

1/ See table footnote for formula.

2/ Caution must be taken not to associate the NTB frequency indices too strongly with the possible magnitudes of the NTB's. It is quite possible that a sector has only a small NTB incidence but that these particular NTB's have large economic effects.

to individual country patterns. (In the former case there is a rank correlation coefficient of about 0.63.) Also, for NTB's the correlation between the U.S. pattern and the average foreign pattern is at the upper end of the scale of country-by-country correlations. Thus, on the average there is a moderate relationship between U.S. and foreign tariff patterns and U.S. and foreign NTB incidence patterns.

It is quite significant that for each country there is a very weak relationship between its own tariff patterns and the NTB incidence pattern. The relationship is weak but positively significant for the EEC and Japan. The relationship is not statistically significant for the United States and Canada, using weighted tariffs. There is a weak positive relationship for the United States when unweighted tariff averages are used.

Table 6 gives unweighted averages of U.S. and foreign tariffs by TC-SIC. Table 7 gives the rank correlations, ranks, and summary statistics of the variables in Table 6. The U.S. tariff rates were converted directly from TSUSA to TC-SIC, the GATT rates and the NTB indices were converted from 4-digit BTN to 5-digit BTN to pure SITC and then directly to TC-SIC via a newly created concordance. Therefore, the GATT rates for some sectors differ from those by IO-SIC in Table 4.

For the TC-SIC, the rank correlation of U.S. tariff rates and NTB frequency indices is slightly positive and a bit stronger than in the

data by IO-SIC. Other general relationships between tariff rates (United States and foreign) and NTB's seem to hold statistically about the same as indicated with the IO-SIC data.

On an overall basis, the data indicate that countries' tariff patterns are moderately similar, countries' NTB patterns are moderately similar, but countries' own tariff and NTB patterns are not.

Table 1.--Nominal tariff rates and non-tariff barrier indices for major trading areas

Source: Compiled from data at the Trade Commission. IO-SIC refers to the Input-Output related Standard Industrial Classification as defined in the 478 sector 1963 U.S. input-output table. Pure SIC refers to the pure SIC codes that are found in the definition of the SIC in 1967. PKR refers to Post-Kennedy-Round tariff rates. The GATT tariff averages and non-tariff barrier indices come from data compiled for previous study: Trade Barriers, Report to Subcommittee on International Trade, U.S. Tariff Commission Pub. 665, Washington, D.C., April 1974.

Note: The U.S. tariffs used 1970 imports as averaging weights. The GATT tariffs use own-country import weights to average to the 4 digit BTN level; no weighting is used to aggregate down to the IO-SIC level.

The GATT rates are PKR rates.

Columns 9 and 16 contain averages of the average tariffs and NTB indices, respectively, for the EEC, Canada, Japan, and the United Kingdom.

Columns 10 and 17 contain weighted averages of the tariffs and NTBs respectively, of several countries. The weights were total shares of 1970 U.S. exports to these countries. If $\bar{t}$ ave. denotes a tariff average, the averaging formula is as follows (the same one was used for NTBs):

$$t_{ave} = 0.034t_{Australia} + 0.0025t_{Austria} + 0.328t_{Canada} + 0.0084t_{Denmark} + 0.0433t_{Belgium} + 0.0608t_{Netherlands} + 0.0547t_{France} + 0.0966t_{Germany} + 0.0494t_{Italy} + 0.0040t_{Ireland} + 0.1707t_{Japan} + 0.0061t_{Norway} + 0.0047t_{Portugal} + 0.02t_{Sweden} + 0.0237t_{Switzerland} + 0.0913t_{United\ Kingdom}.$$

The weights sum to unity.

The IO-SIC sectors presented are those which had trade data assigned to them. IO-SIC sectors which do not produce goods are not shown here but are shown in Appendix D.

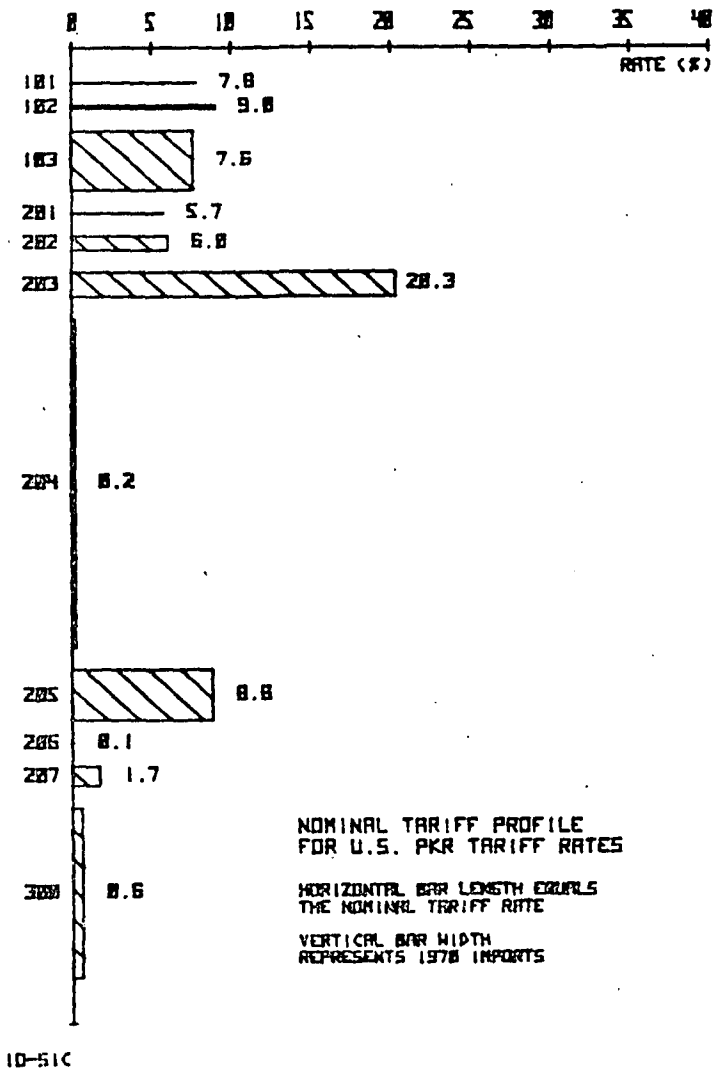

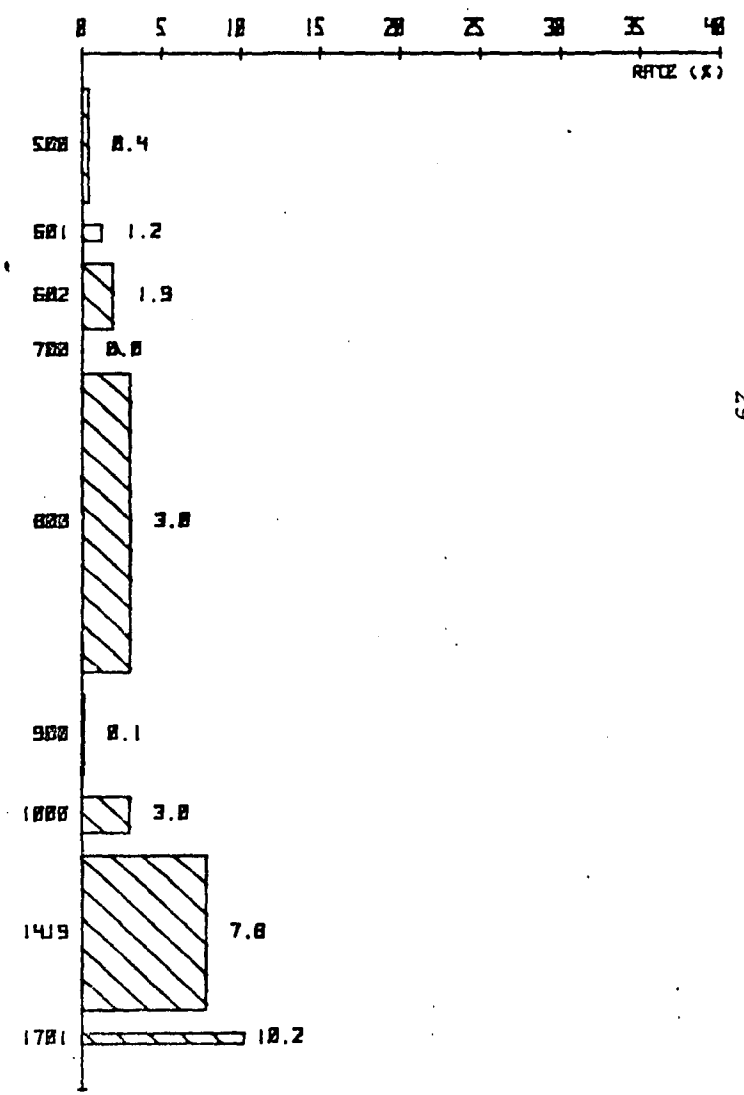

CHART 1--Cont.

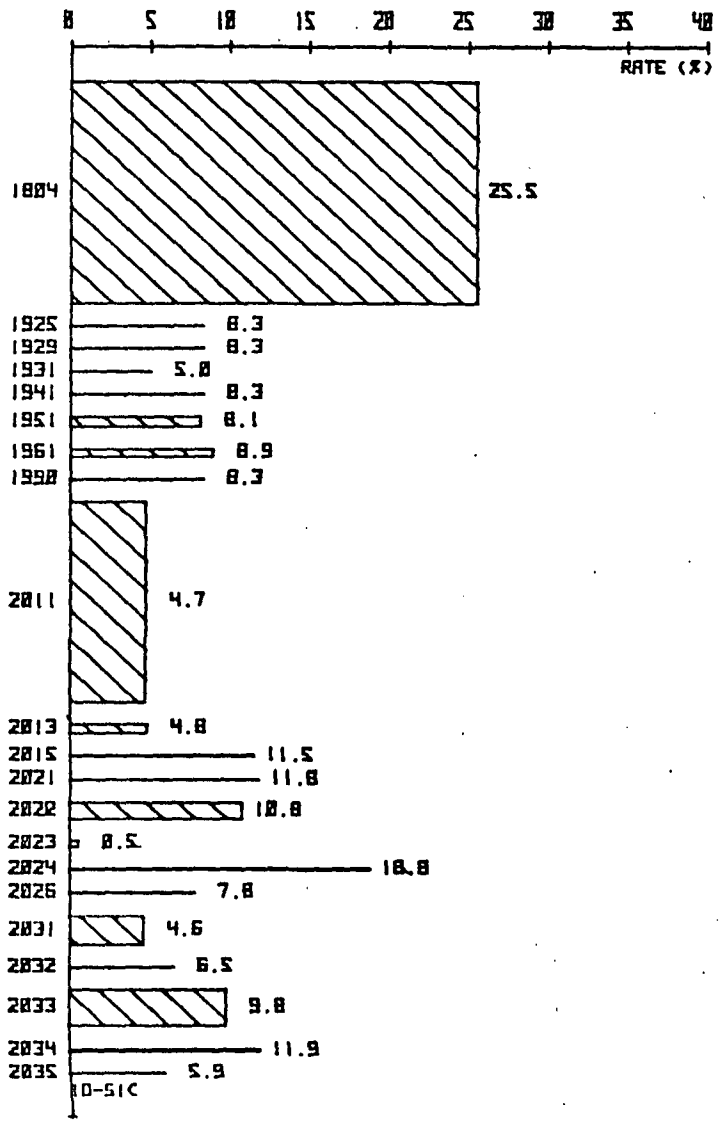
Nominal tariff profiles for U.S. Post-Kennedy-Round (PKR) tariff rates



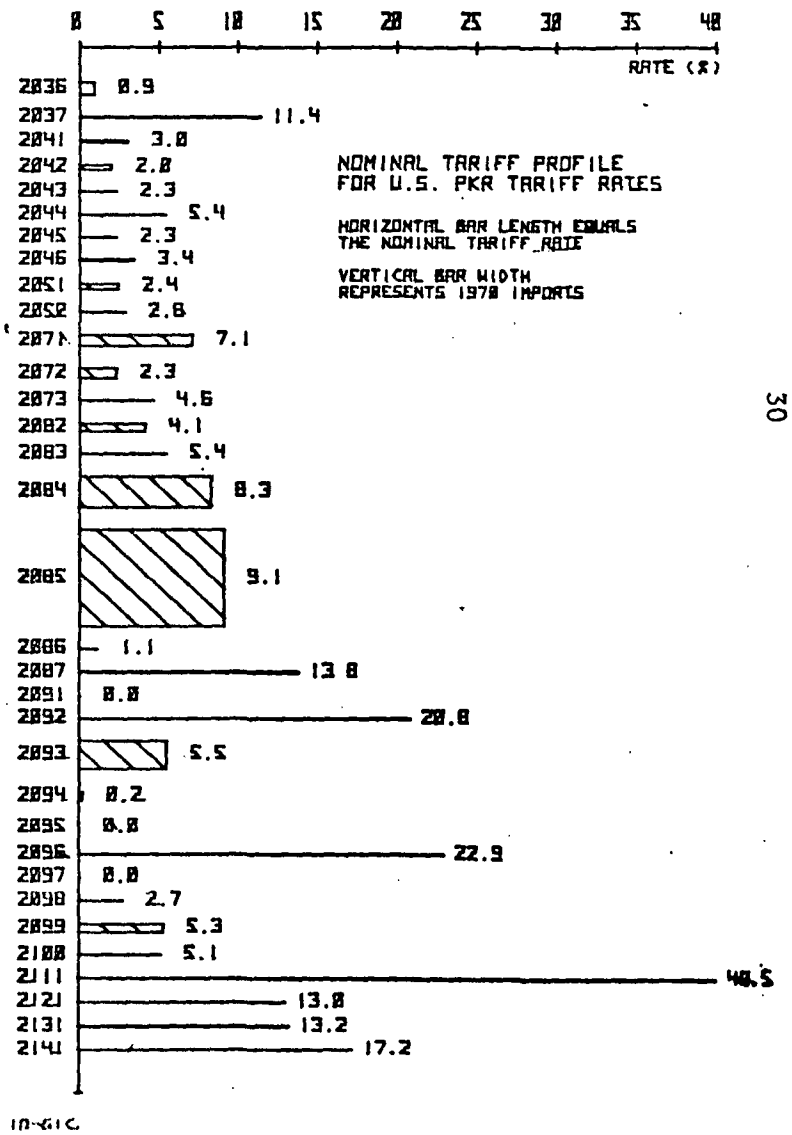


CHART 1--Cont.

Nominal tariff profiles for U.S. Post-Kennedy-Round (PKR) tariff rates

Source: The PKR nominal tariff rates come from column 4 of Table 1. The 1970 import weights that are represented by bar widths were calculated from data of the U.S. International Trade Commission.

Note: Tariff profiles are intended as visual aids in summarizing average tariff weights and the amount of trade affected by those tariff weights. The shaded area of the bar roughly represents the duty collected on imported goods that are thought to be competitive with U.S. products.

Source: Compiled at the U.S. International Trade Commission.

Note.--The numbers in parentheses refer to the column numbers of the data in the previous table.

The short abbreviated names at the beginning of the table and in the summary statistics are assigned names of the variables in the Trade Commission computer databank.

Data with identical values are given the same rank. Tied ranks are adjusted for in the Spearman rank correlation coefficient tabulations.

Table 3.--Nominal tariff rates and non-tariff barrier indices for major trading areas

(Using simple tariff averages)

THE UPPER RIGHT HALF OF THE MATRIX CONTAINS THE SPEARMAN RANK CORRELATION COEFFICIENTS. THE LOWER LEFT HALF CONTAINS THE "T" SIGNIFICANCE STATISTICS. THE NUMBER OF DEGREES OF FREEDOM IS 372

See source on following page.

Source: The upper matrix--variables 2, 3, and 4 are from columns 2, 3, and 4 of table 1; variables 5, 6, and 7 are from columns 2, 3, and 4, respectively, of table 3.

The lower matrix--variables 2-7 are from columns 5-10 of table 1, and variables 8-13 are from columns 5-10 of table 3.

CHART 2

Bar graph of differences between U.S. nominal tariff averages and foreign nominal tariff averages

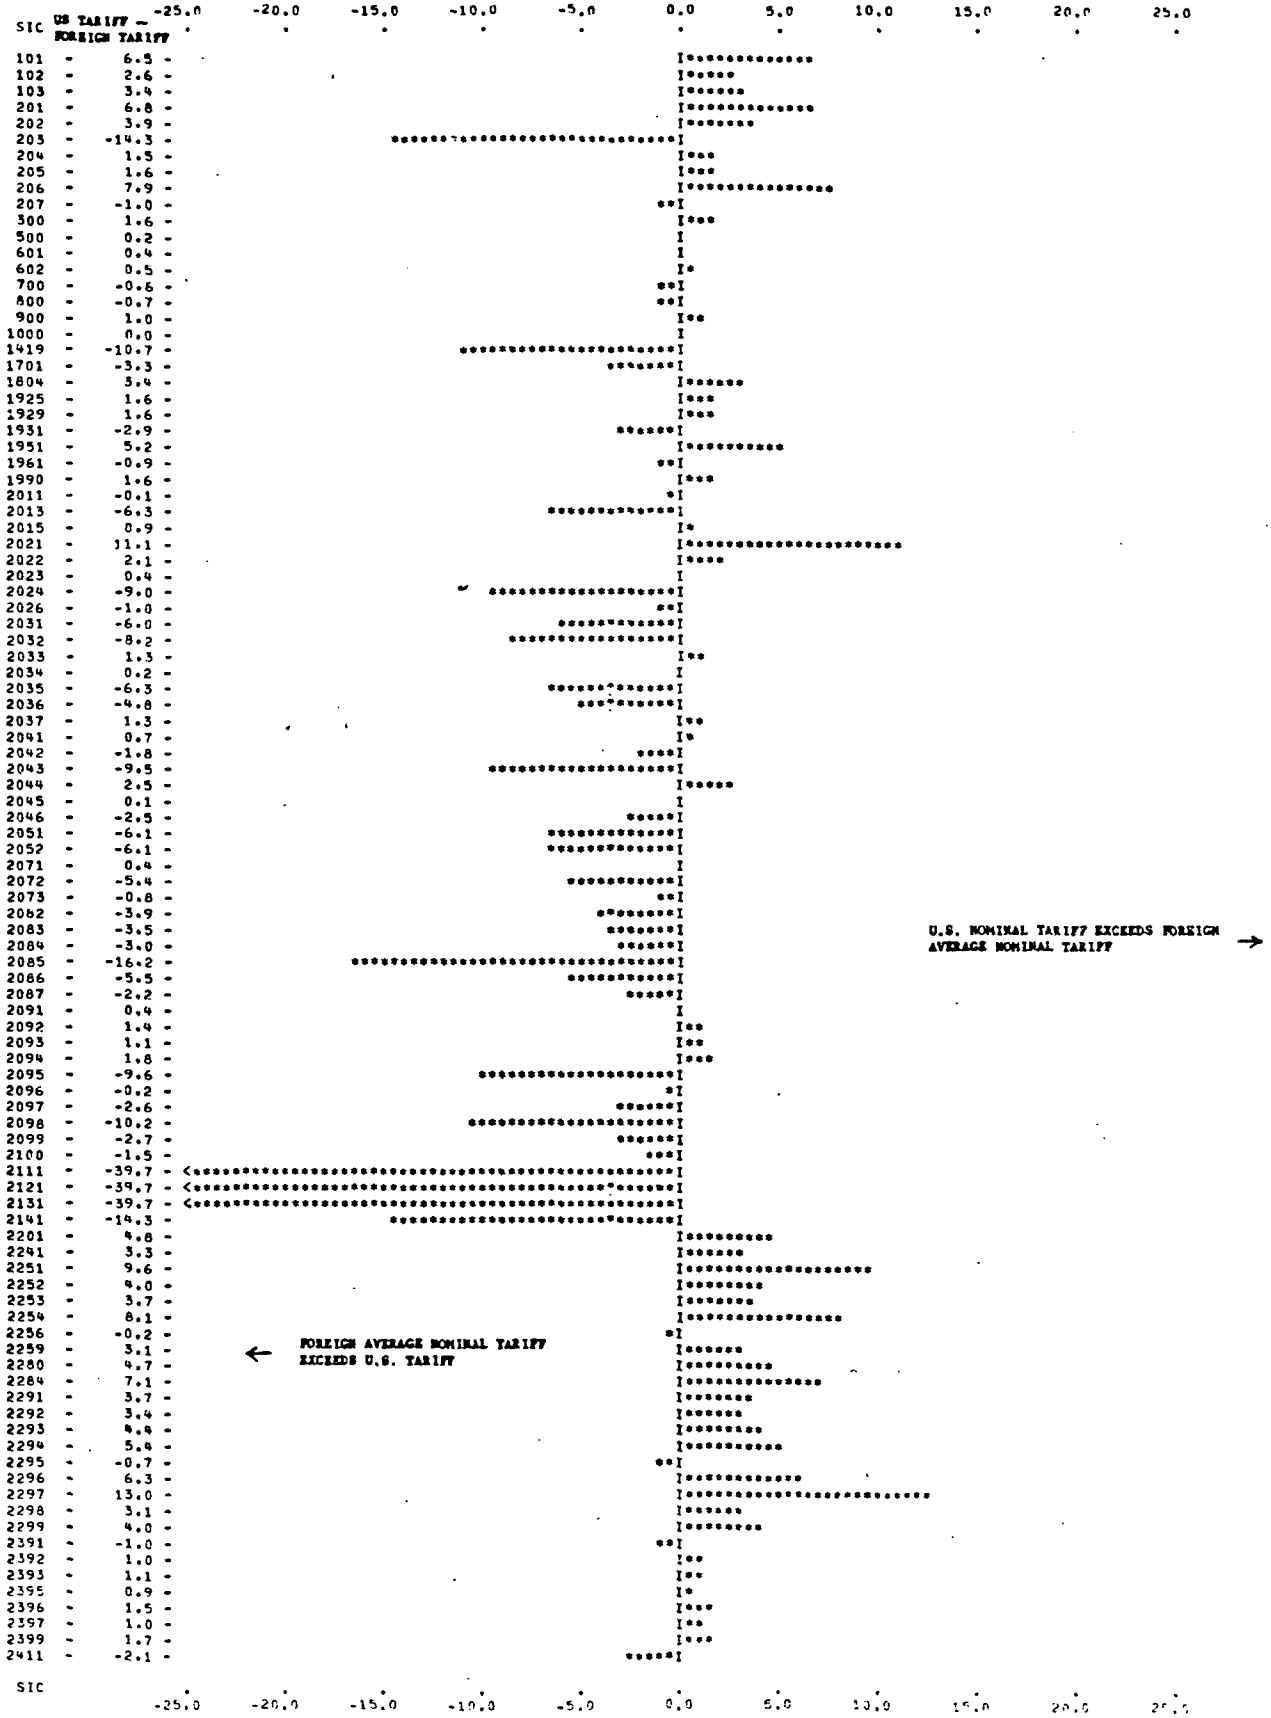

CHART 2--Cont.

Bar graph of differences between U.S. nominal tariff averages and foreign nominal tariff averages

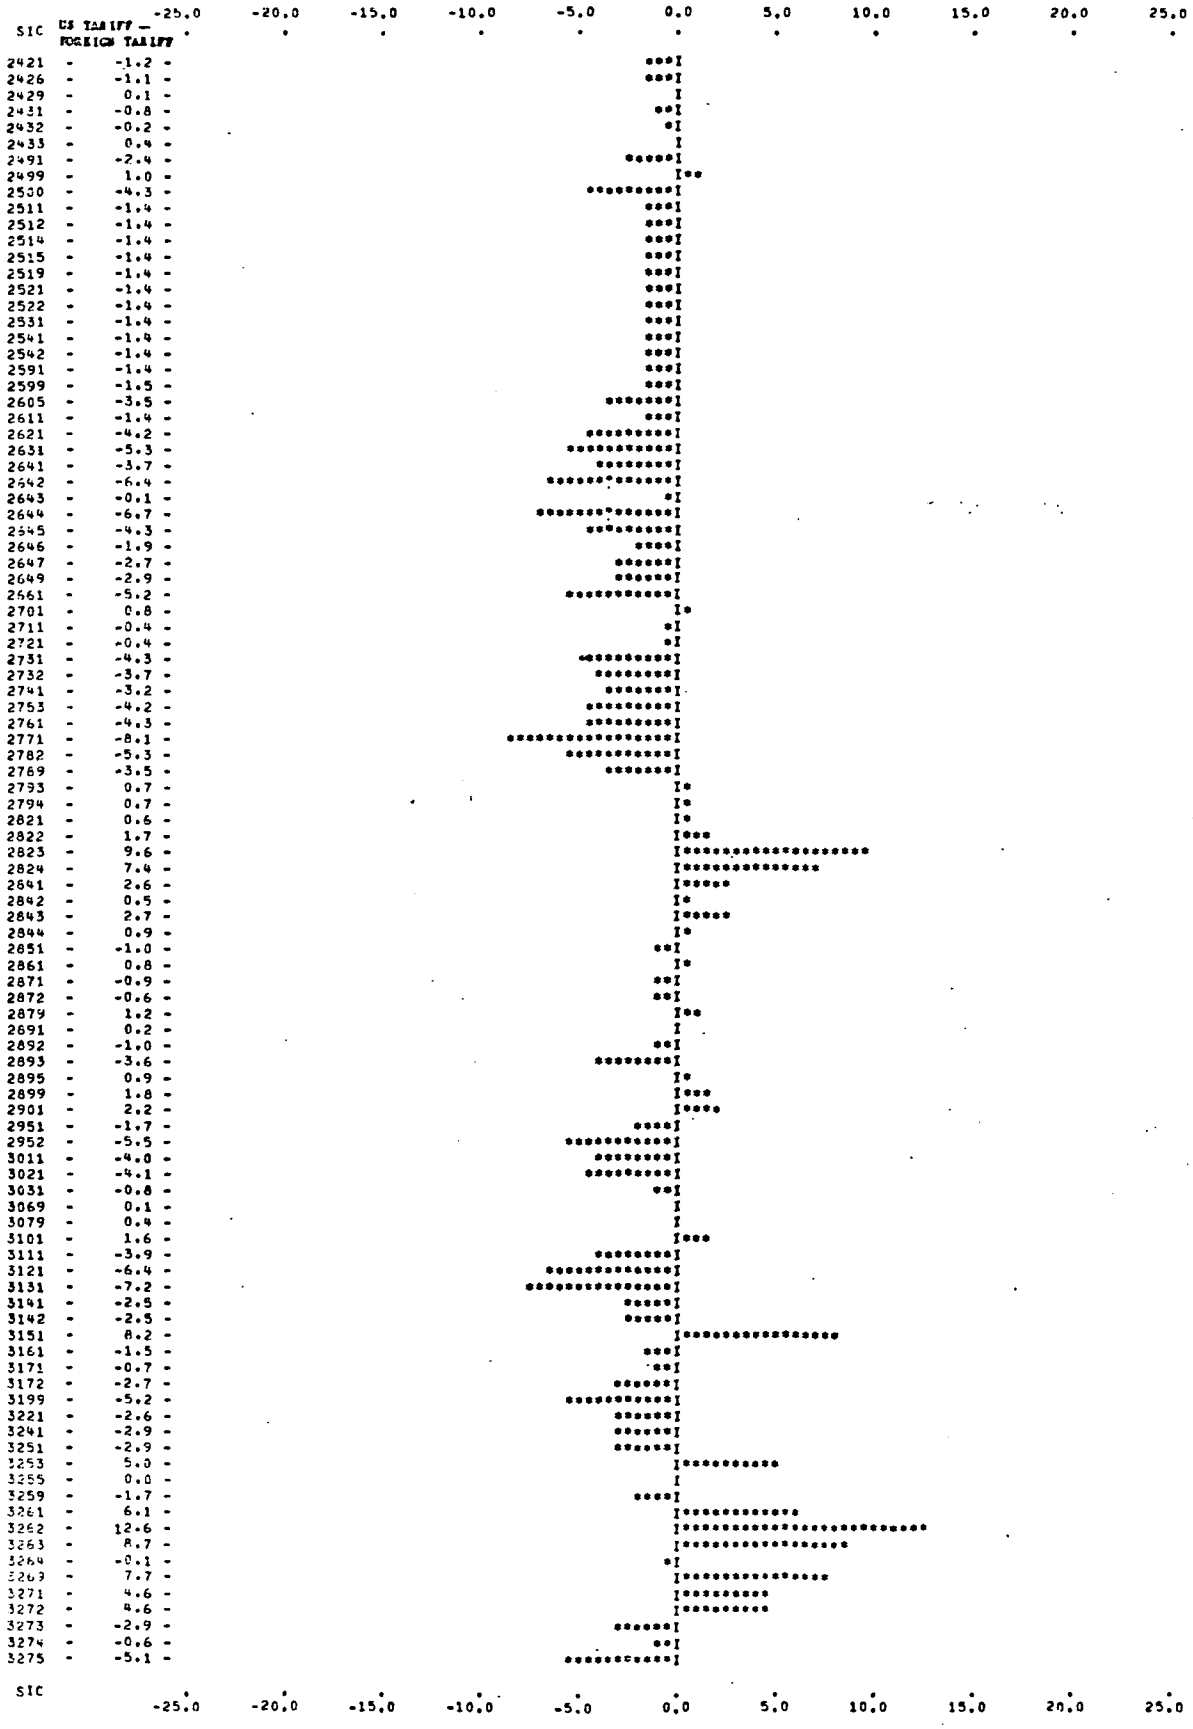

CHART 2--Cont.

Bar graph of differences between U.S. nominal tariff averages and foreign nominal tariff averages

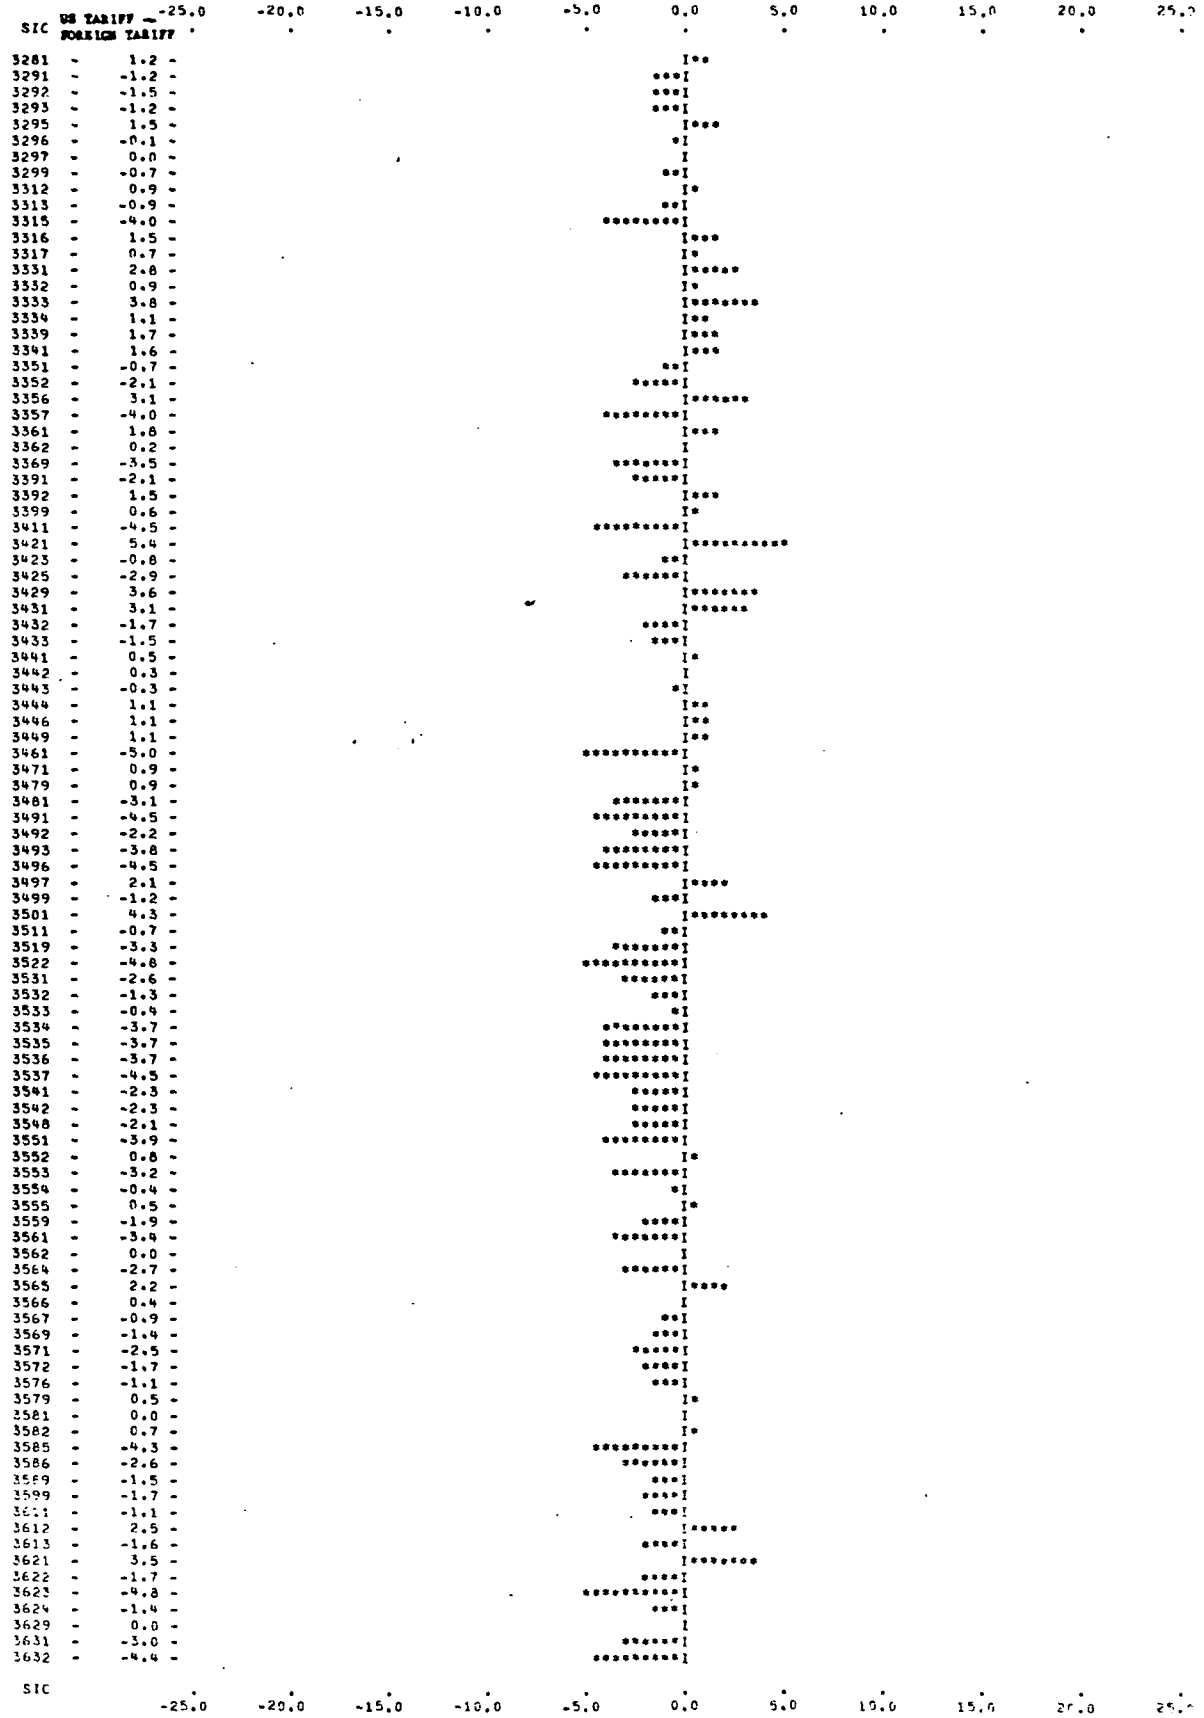

CHART 2--Cont.

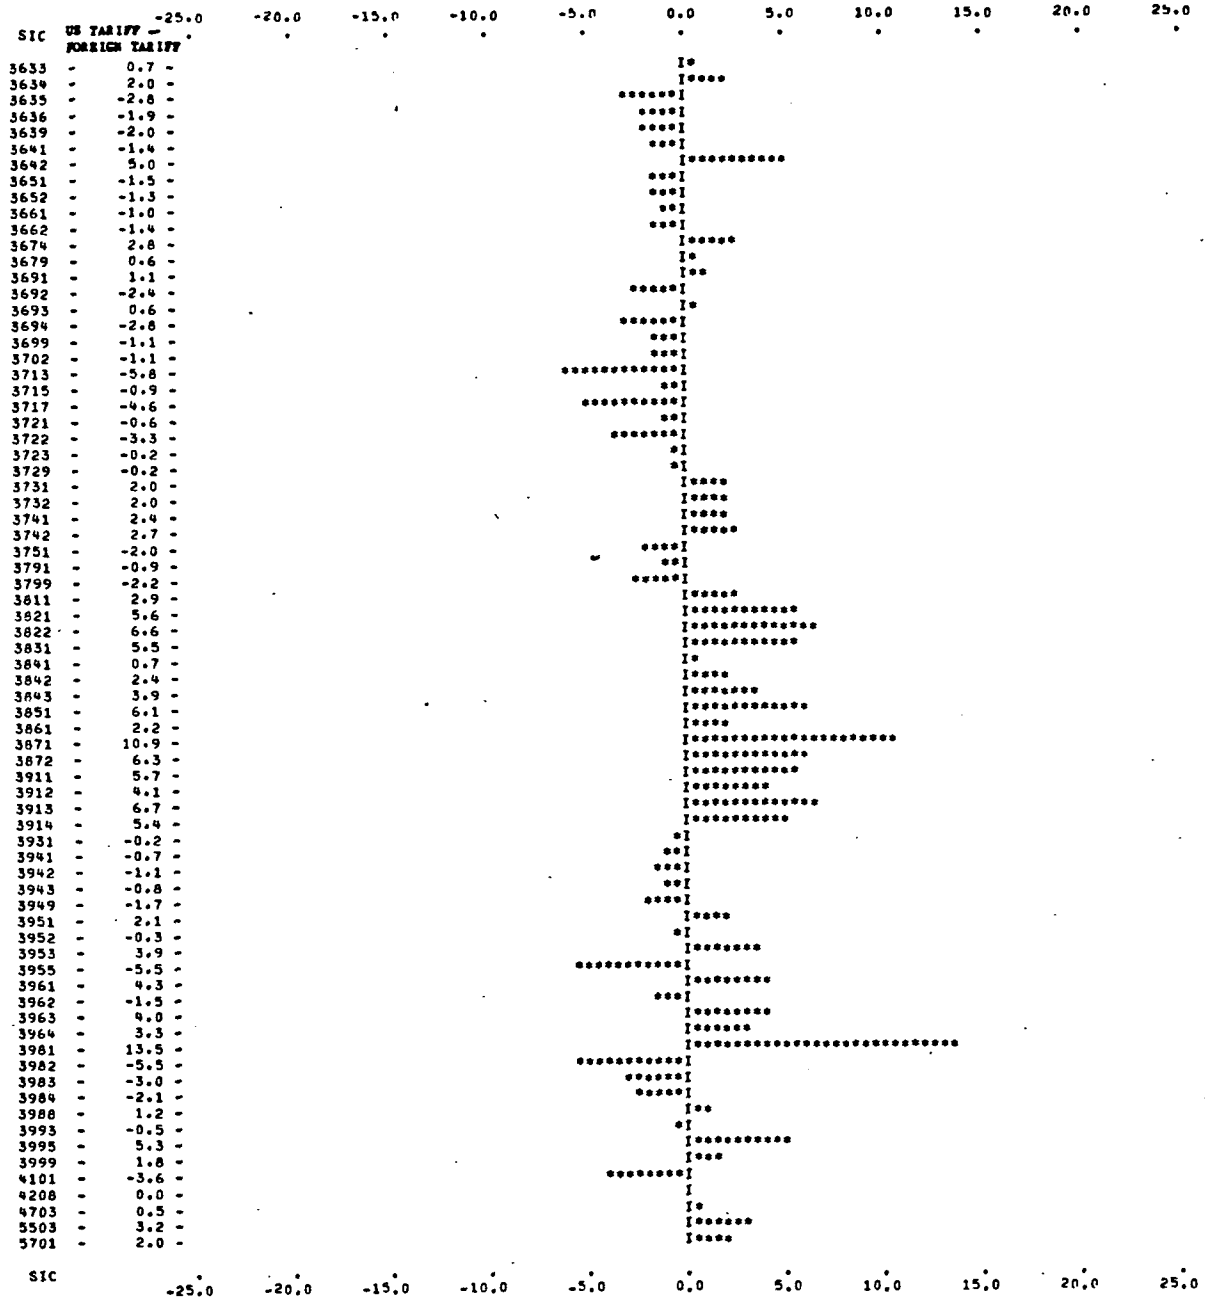
Bar graph of differences between U.S. nominal tariff averages and foreign nominal tariff averages



Source: The difference between the U.S. PKR nominal tariff rate and foreign PKR nominal tariff rate is found by subtracting column 10 from column 5 in table 3. Thus the bars represent differences between simply averaged U.S. and foreign tariffs. The reader must keep in mind the weaknesses of the concordance procedures used in arriving at these tariff rates.

PART II

Effective Tariff Protection in Major Trading Countries

In considering tariff protection, there are many meaningful modes of analysis. One approach is to consider the linkage between product tariffs, imports, domestic prices, and domestic production. The objective is to take account of (and hopefully measure) the effect of a tariff on a tariff inclusive import price. A tariff that "matters" will then allow the producer to charge more for an equivalent domestic product and thus continue its production in the face of import competition. A "probable effects" analysis of a tariff change would then require further information on domestic supply and demand price responses (elasticities) in order to determine the production, employment, and trade effects of the tariff change. Analysis of this type (termed partial-equilibrium) is useful and necessary in considering probable economic effects of tariff changes during a tariff negotiation. This analysis would be even more useful if some overall economic modeling framework were applied to allow measurement of net effects of trade on production and employment. 1/

The shortcoming of partial equilibrium analysis is its limitation only to the product price effect. If tariffs indeed do matter, then broad changes in the tariff structure should produce broad changes in the domestic price structure. These should significantly influence

1/ Thus, when domestic industry losses are contemplated from a tariff cut, any possible gain due to other countries' tariff cuts should also be calculated.

not only product prices, but also domestic production costs. It is the latter consideration of production cost effect that is the weakest theoretical link in most partial equilibrium analysis. 1/

The Effective Tariff (ET) approach is an attempt to overcome the partial equilibrium approach's neglect of the input cost effects of tariffs. Although it introduces other shortcomings which result basically from the lack of data needed to do complete calculations, 2/ it does provide a more general consideration of tariff protection and its economic effects. The superiority of one approach over the other depends partly upon the questions asked and the overview of protection desired. It also depends partly on the success of the two approaches in empirically exploring the past economic effects of protection and changes in protection. The ET concept tries to measure the net effects of all tariffs in the economy on each sector. It gives the net effect as percentages of what value-added would be without any protection (i.e., free-trade value-added).

In this study, value-added is defined as total sales value minus purchased material inputs and services. This definition makes value-added

1/ It is true that the industry price response measures may be influenced by the industry's material input cost structure and thus would be partially accounted for. Profits in an industry that had many purchased inputs would probably be more sensitive to product price changes than for one that had few input costs to consider.

2/ A complete study of the effect of protection on production costs would need a thorough knowledge of input requirements, of possible substitutions that might occur with relative input price changes, of supply price responses, and other information. Much of the economic literature devoted to effective tariff protection deals with models which try to take account of the shortcomings that are embedded in the calculations of effective rates. See Effective Tariff Protection, edited by H. Grubel and H. Johnson, General Agreement on Tariffs and Trade, Geneva, Switzerland, 1971.

the net earnings from production which are paid to investors as profits and to workers as wages. 1/ The ET concept is an attempt to measure how tariffs (affecting both product prices and input costs) influence profits and wages in an industry. The base of measurement is what the profits and wages fund would be if there were no protection at all.

The Calculating Formulae

Define

t_i nominal tariff on the product of the i 'th industry.

P_i, P_i' free trade and protection product prices, respectively.

Practicality dictates the assumption that $P_i' = P_i(1 + t_i)$ (i.e. tariffs matter 100 percent).

V_i, V_i' free trade and protected value added per unit output.

Then: $V_i \equiv P_i - \Sigma_j a_{ij} P_j$ where a_{ij} is the physical amounts of industry j's output used as an input to industry i. (Note that $\equiv$ means a definition). 2/

1/ This definition was chosen in order to use the 1963 Input-Output (IO) table to estimate sector input costs. The definition also allows the use of the model described in Part III.

2/ One of the limitations in calculating the ET rate is that input coefficients are assumed to be constant irrespective of relative input price changes. This is unrealistic. Also, no assumptions are made on how capital and labor might respond to protection-caused changes in the value-added fund. However, even though the measurement assumes linear production relations (no substitution, no scale economies) and is static (no supply or demand responses over time), it can be strongly argued that the measurement problems of the variables in even the most simple ET formulas are large enough to make more complicated formulas empirically useless.

$$ET_i = \frac{V_i'}{\frac{P_i'}{1 + t_i} - \sum_j a_{ij} \frac{P_j'}{1 + t_j}} - 1$$

$$(1) \quad ET_i = \frac{V_i'}{\frac{1}{1 + t_i} - \sum_j \left(\frac{a_{ij} P_j'}{P_i'} \right) \frac{1}{1 + t_i}} - 1$$

Formula (1) is the calculating formula used in the calculation of ET rates in this study. 1/

One can also start with the definition and derive formula (2) which is useful for expository purposes.

$$T_i = \frac{V_i' - V_i}{V_i}$$

$$= \frac{P_i (1 + t_i) - \sum_j a_{ij} P_j (1 + t_i) - \left[P_i + \sum_j a_{ij} P_j \right]}{V_i}$$

$$= \frac{P_i t_i - \sum_j a_{ij} P_j t_j}{V_i}$$

$$(2) \quad ET_i = \frac{t_i - \sum_j \left(\frac{a_{ij} P_j}{P_i} \right) t_j}{V_i / P_i}$$

Formula (2) shows that ET_i is larger (a) the larger the tariff on output, (b) the smaller the weighted sum of the tariff on inputs to production, and (c) the smaller the value-added share of total output.

1/ In formula (1), input weights $\left[\frac{(a_{ij} P_j')}{P_i'} \right]$ are observed values.

The $\left[\frac{(a_{ij} P_j')}{P_i'} \right]$'s as well as the V_i coefficient are taken directly from an adjusted version of the 1963 input-output table.

On the average, ET rates tend to be higher than NT rates, because the denominator in formula (2) is less than one. This will not be true, however, if the weighted sum of the tariffs raising input costs is large enough. It is even possible for the weighted sum of input tariffs to exceed the output tariff. This leads to a negative ET rate. Such a rate means that when the entire tariff structure is considered, the net effect harms rather than helps wage and profits in the industry. It is also possible that a particular ET rate will be infinitely large. 1/

Calculations of Effective Tariff Rates

The ET rates were calculated using the 1963 U.S. input-output table and the nominal tariff averages for IO-SIC sectors shown in Part I. All of the concordance and averaging problems involved in obtaining the nominal rates in Part I are therefore included in the ET calculations. In addition, there are some problems in using an input-output table as a source of weights for input tariffs.

Calculations were done using U.S. tariffs from U.S. sources plus United States and foreign tariffs from GATT sources. The ET rates derived from U.S. tariff sources are considered better for U.S. ET rate comparisons among industries. However, for comparisons of U.S. and foreign ET rates, the GATT tariff sources were the only realistic alternatives

1/ If protection is large enough on a very noncompetitive industry, it can survive. An industry which would not be able to cover its input costs under free trade (meaning negative free trade value-added) would survive with high enough protection. Calculation of ET rates for these industries would approach infinity from the plus or minus side. For a detailed explanation see: Effective Tariff Protection and Comparative Advantage in Southern Africa, Vernon Roningen, Unpublished Ph.D. dissertation, Columbia University, New York, N.Y., 1972, pp. 42-49.

available. The use of the U.S. IO table for foreign ET calculation assumes that foreign countries' inter-industry production structures are identical to those of the United States. The lack of foreign input-output tables of comparable size and sector definition led to the use of the U.S. table for all ET calculations. 1/

Even though the tables in Part I show one tariff average for each sector, the products included in many sectors' output are both of an intermediate and final nature. For example, the average tariff rate covering the final output products of the textile sectors (sold to consumers and other industries) may not be the same as the rate covering the output products of the textile sector sold only to other industries as manufacturing inputs. In order to allow for different tariff averages for an industry's output and the industry's input into other industries, two vectors of tariff averages were calculated. The output average is the one covering all products shown in the tables in Part I. The input vector omits AVE's of TSUSA numbers which are designated as final manufactured products on the Trade Commission tapes. 2/

Even though this procedure tried to provide different tariff averages for input and output tariffs, the averages turned out to be similar for most IO-SIC industries. 3/

1/ The use of one I-O table for various countries' ET calculations precludes ET differences due to IO table definitional differences or structural differences.

2/ See Appendix C for the details on how this input tariff sector was prepared.

3/ Tables of both NT and ET averages in the study contain only the overall NT average for I-O SIC sectors. Thus, when comparisons are made of NT and ET rates, the single vector of NT rates shown and used is not exactly the same as the input actually used in the ET calculations. However because there was so little difference between the input and output sector and because of space limitations, only the average NT sector was presented in the text. Appendix D contains the actual tariff vectors used along with alternative ET calculations using only the one NT (output) vector.

One expected result is that the overall variation in ET rates is much greater than that of nominal rates. This is shown in the summary statistics in Tables 9 and 11 where the coefficient of variation for ET rates is well over twice that of nominal rates. 1/

Table 13 presents overall weighted tariff averages for 1965, 1970, and PKR nominal and effective tariff rates. These are more meaningful for assessing overall effective tariff protection than the simple averages appearing in Tables 9 and 11. It is known that free trade value-added weights are appropriate for the aggregate of ET rates. 2/ It can also be argued that a value-added weighted average effective tariff rate covering all sectors of the economy roughly represents the total cost of protection. This is a static cost measure in the sense that if resources were reallocated on a costless basis to industries and products with zero ET rates, the value-added weighted average rate would represent the loss in real income incurred by operating protected and therefore inefficient industries. This cost estimate is an upper range estimate since, if protection were removed, exchange rate changes and price changes of nontraded goods and services would produce a lower cost estimate. 3/

On the basis of Table 13 it would appear that the cost of present protection in the United States is a loss in real income of about

---

1/ This statistic varies greatly if one or more ET rates becomes very large.

2/ See: The Structure of Protection in Developing Countries, Bela Belassa and associates, Johns Hopkins Press, Baltimore, 1971; and Effective Tariff Protection and Comparative Advantage. . ., p. 296, op. cit.

3/ See: Effective Tariff Protection . . ., op. cit., Ch. VIII. The argument assumes an equilibrium in the factor markets.

five percent. This is down from an 8 or 9 percent cost in 1965 but is still more than half the 1965 cost. Considering that these costs do not include those of non-tariff barriers, further tariff negotiations can indeed play a role in increasing national welfare. It is also evident that if tariffs were eliminated, the adjustment costs (in term of factor returns diminishing in certain sectors) would probably be as great as those occurring during the Kennedy Round tariff reductions.

Even though the weights used are not quite appropriate, the overall nominal tariff averages in Table 13 indicate that elimination of tariffs would probably not have a very large overall price effect. Thus, tariff reductions probably could not be counted upon as the chief weapon in a major anti-inflation effort.

As in any statistical evaluation, what is true for the average is not by definition true for all observations. Hence references to individual sector data will require careful examination of the relative behavior of nominal and effective rates for each sector.

Table 8.--Effective tariff rates for major trading areas using import weighted nominal tariff averages

Source: The nominal tariff averages for the U.S. in columns 2, 4, and 6 come from columns 2, 3, and 4 respectively of table 1. These nominal rates plus the GATT nominal rates from table 1 were used, in conjunction with an adjusted version of the 478 sector 1963 U.S. input-output table, to calculate the effective tariff rates shown.

Note: Details of the calculation procedures are given in Appendix C. The IO table adjustments basically were the exclusion of transferred secondary products, the exclusion of indirect taxes, and the adjustment of protected value-added figures to avoid zero or negative free trade value-added coefficients, assuming reasonable price changes. After these adjustments, any effective rate exceeding 9,999.9 percent or less than - 100.0 percent was pegged at 9,999.9 percent. This was done to avoid having to adjust correlation programs for discontinuities in effective rates, but extremely high and extremely low negative rates have been omitted from the Tables.

The ET rates shown for data from TSUSA sources used the given nominal rate as the output tariff slightly different input-oriented tariffs as input entries. See Appendix C for an explanation and Appendix D for sample calculations of ET rates with and without this procedure.

Source: The nominal tariff averages for the U.S. in columns 2, 4, and 6 come from columns 2, 3, and 4 respectively of table 3. These nominal rates plus the GATT nominal rates from table 3 were used, in conjunction with an adjusted IO table, to calculate the effective tariff rates shown.

Note: See the note of table 8 and Appendices C and D for details of calculations.

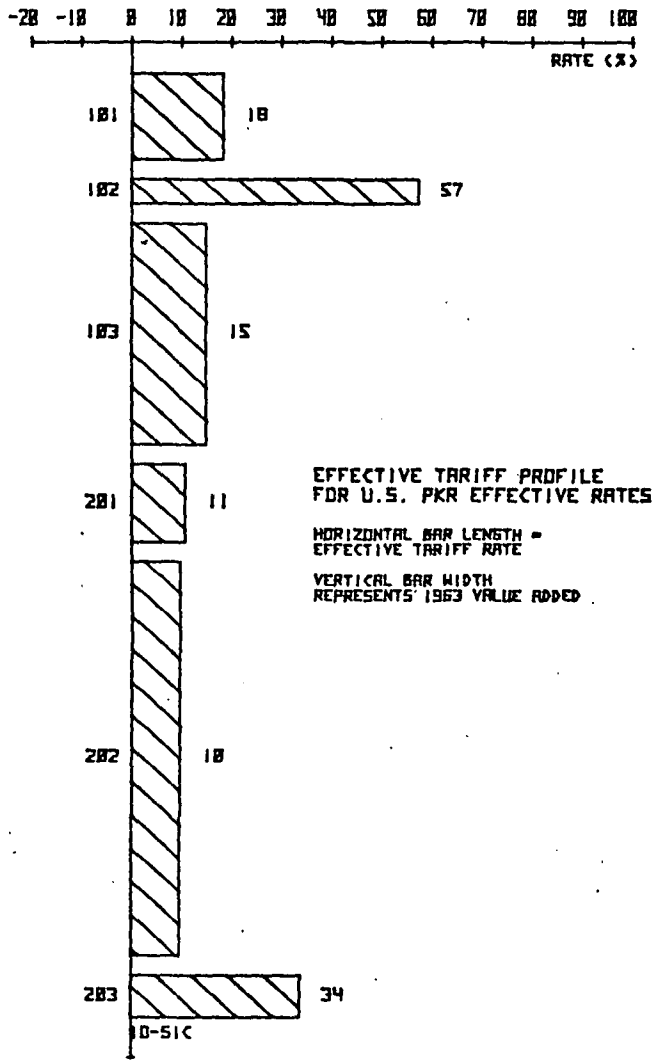

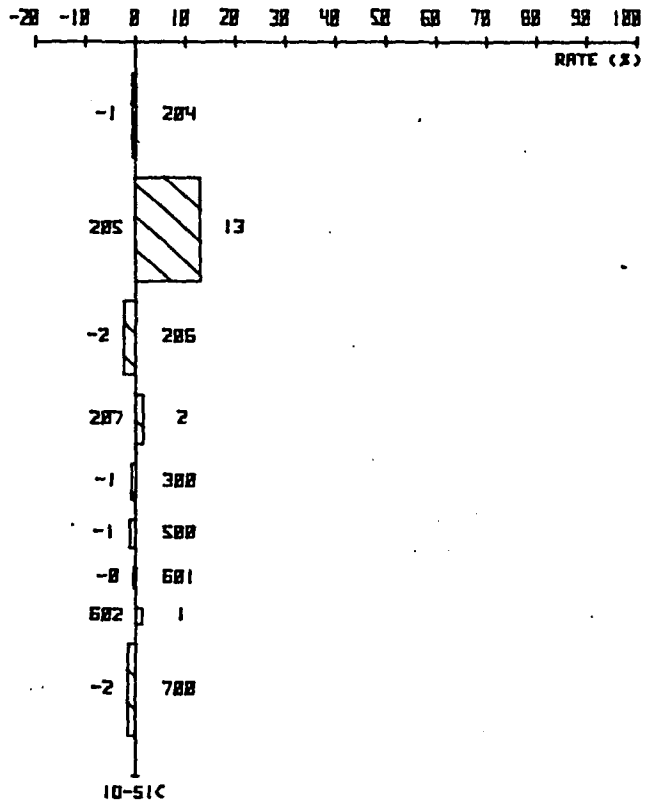

CHART 3--Cont.

Effective tariff profiles for Post Kennedy Round (PKR) effective tariff rates for the United States

Source: The U.S. PKR effective tariff rates are from table 8, column 7. The 1963 value-added weights representing the bar width are from the 478 sector input-output table for the United States.

Note: To the extent that value-added has grown roughly proportionally in all sectors of the economy, the 1963 value-added weights are rough approximations for sector sizes in later years.

A bar to the left of the origin indicates a negative average effective tariff rate for the sector. The sectors shown are those producing traded goods. It should be noted that sectors which do not produce traded goods also have effective tariff rates.

A crude interpretation of the shaded area of a bar would be that it represents the amount of subsidy received by the factors of production in a sector because of the tariff structure. The area of a bar to the left of the origin represents the net loss incurred by factors of production in that sector beacuse of the tariff structure.

Table 13.--Overall averages of nominal and effective tariff rates for the United States

Year	Using import weights on nominal tariffs		Using unweighted nominal tariffs	
	Nominal	Effective	Nominal	Effective
	Percent	Percent	Percent	Percent
1965	6.9	8.1	7.8	9.2
1970	5.7	7.6	6.1	6.7
PKR	5.1	5.4	5.2	5.6

Source: Compiled at the U.S. International Trade Commission from data in tables 8 and 10.

Note.--Nominal rates were aggregated over 470 sectors using 1963 total shipment values from the input-output table. Effective tariff rates were aggregated by using versions of 1963 free-trade value added from the tables. The use of a single 1963 free-trade value added figure for aggregation was not the best procedure from a theoretical point of view, but after eliminating several anomalies from the input data, satisfactory averages were derived.

PART III

TOWARDS MEASUREMENT OF COMPARATIVE ADVANTAGE

An interesting question for trade negotiations is "wherein lies U.S. comparative advantage (CA) in international trade?" A theoretically and empirically sound ranking of all sectors of the U.S. economy by their comparative advantage would greatly aid policymakers in rational choices of negotiating strategy. The ultimate goal should be an operable model which would predict the costs of and the benefits from proposed changes in the protection structure of both the United States and its trading partners. 1/

This section presents a model (based on the effective tariff concept) which points to some crude comparative advantage measures that would add to the usefulness of effective tariff rates. 2/ The model is a step towards the construction of something more general; it forces researchers to face up to the data and methodology problems that would come with a more useful predictive model.

1/ An example of such a model of a linear programming type is presented by Evans for Australia in Effective Tariff Protection, op. cit.

2/ The model is found specifically in the following three sources:

1. Findlay, R. "Comparative Advantage, Effective Protection, and the Domestic Resource Cost of Foreign Exchange," Journal of International Economics, I (May 1971), pp. 189-204.
2. Kemp, M., The Pure Theory of International Trade, Prentice-Hall, Englewood Cliffs, N.J., 1964.
3. Roningen, Effective Tariff Protection, op. cit.

The more complicated models, such as the Evans one mentioned previously, add complexity and a dynamic formulation.

The Findlay article (ref. above) and others have shown that effective tariff rates come close to measuring comparative advantage in a static sense under certain conditions.

The chief benefits of the model are that it forces an operational definition of comparative advantage and that it combines data from various sources in a logically sound framework. The variables in the model are defined below:

Let:

Vi=value-added per unit output per year in the i'th industry
Wi=wage per employee per year in the i'th industry
ri=rate of return (%) to capital in the i'th industry
Li=employees per unit output per year in the i'th industry
Ki=physical capital per unit output in the i'th industry

If Vi is defined as it is in Part II, then $Vi=riKi + wiLi$

A useful set of variables is the ratios Ki/Vi and Li/Vi. They give the amount of capital (in $) and the number of employees required to produce a dollar of value-added in the i'th industry in a year. These two numbers measure a year's resource requirements for a dollar's value added at observed prices (which are embedded in Vi, $Vi=P_i-\Sigma_j a_{ij} P_j$ from Part II). 1/

The capital and labor requirements can be plotted on a graph for comparison between sectors. If employees were all receiving the same wage and capital were earning the same return in most industries, then $ri=r$ and $wi=w$ and $Vi=rKi + wLi$ for most industries. This would mean that most points would lie on the straight line shown in Figure 1.

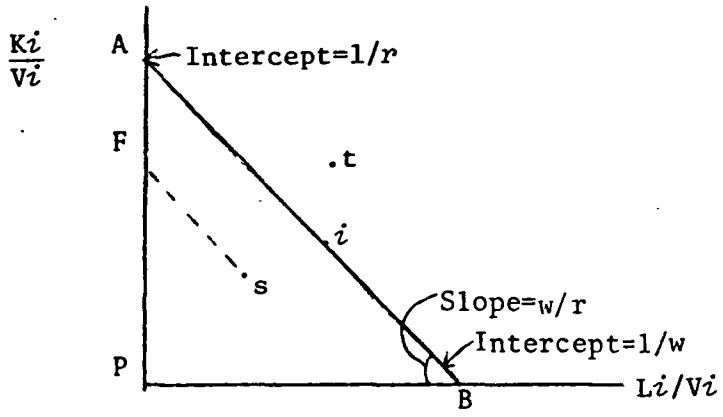
A point such as the one for the i'th industry would lie on the line AB if its factors were earning w and r. If a point were at s,

---

1/ Practically, prices and value-added in these calculations are averages of the actual prices and amounts of value added accompanying the many products produced in a sector.

Figure 1

Capital and Labor Requirements Per Unit Value-Added



such an industry would be using less factors (capital and labor) to produce a dollar of value added. It would therefore be more efficient and its factors would earn $wi>w$ or $ri>r$ or both.

An industry at point t would take more factors to produce a dollar of value-added and hence would be less efficient than a point on the line AB. Either its employees would receive a lower wage or its investors would receive less profits or both. To the extent that resources are mobile over time, they would want to transfer from such industries to those such as i or s where they would earn more.

If some industries (such as s) were not on line AB, the use of the ratio w/r could be used to convert labor into capital units and sum them to FP, a measure of total factors used per dollar of value-added at average or "overall" relative factor prices. Thus, the distance FP would be a total factor cost measure, and its reciprocal could be defined as a measure of Comparative Efficiency(CE) for the sector "s" (1/FP≡CE). It would be the amount of value-added generated per unit factor (in capital units) in an industry at the average relative rate of factor return. It could be compared with CE measures in other sectors. Such a measurement assumes that capital values and numbers of employees move more slowly in time than prices and that capital and labor do move from sector to sector in response to prices as they affect their earnings. These are reasonable economic assumptions which are embedded in most economic analysis in one form or another. The model is static and therefore does not specify how fast resources will

move in response to price incentives (such information is the core of operation of a dynamic model).

The CE measure is not only one of relative efficiency between domestic industries, but it is also the only one of relative comparative efficiency in traded goods. If all output is tradeable, then a dollar earned (from adding value to any product) can be spent on any import at the given exchange rate. 1/ It is obvious that factors in industries such as s, because they use less of themselves to earn a dollar and thus a dollar's worth of foreign exchange, can buy more imports than the factors in industry t. Conversely, less factors are used to earn a dollar or a dollar's worth of foreign exchange via exports in industry s than in other industries. Hence the CE measure covers true comparative efficiency in the economic sense both in comparison of relative economic efficiency among domestic sectors and in relative efficiency in producing goods for foreign markets.

Part II showed that protected unit value-added (V) and free trade unit value-added (V^F) are related by the effective tariff rate, i.e., $Vi=Vi^F\ (1+ETi)$.

Assuming that points on the line AB in figure 1 represent an equilibrium in a protected price structure, application of the ET rate to Vi will give the free trade amount of factors needed to produce a dollar of value-added assuming protection is removed. 2/

1/ If some sector's output is not traded, the same efficiency arguments apply.

2/ This statement also involves an assumption of no relative factor price changes or non-traded goods price changes or exchange rate changes occurring when protection is removed. These assumptions must be paid some attention in terms of a more realistic model. (See Evans and Roningen, op. cit); but as a first approximation and considering measurement problems for even the simple model, these assumptions are not too restrictive.

Thus an ET rate of 100 percent would mean that $Vi^F = Vi/(1+100/100) = Vi/2$. Then twice as many resources would be needed to produce a dollar of free trade value-added. The free trade resource requirements of such a sector would be represented by a point twice as far from the origin as the protected point.

Conversion of points in Figure 1 to their free trade equivalents can be done by multiplying the protected point by one plus the ET rate. A definition of comparative advantage would then be the above comparative efficiency measure adjusted to the free trade level stated by the effective tariff rate.

Such a model gives a logical definition of comparative advantage in terms of total resource productivity and protection-caused divergencies between domestic and foreign prices. Comparative advantage so defined sounds reasonable and simple, although the measurement problems are difficult.

The Data

Various data sources were used to derive measures for the model described above and to use regression analysis in testing various hypotheses. Data variables will be simply defined in the text where necessary and will be referenced by their computerbank names. Appendix F contains sources for the variables.

The problems involved in applying data to the model described in Figure 1 are readily apparent when one looks at the scattered data points in Charts 5 and 6. Here, for most IO-SIC manufacturing sectors,

are plots of capital per unit value-added versus labor per unit value-added. Chart 5 uses data for 1967 while Chart 6 gives 1970 data. A hypothetical equilibrium line has been drawn in each graph. The intercepts were calculated using the average wage (total wage bill/total employment) and the average rate of return to capital (total value-added minus (taxes plus depreciation) minus wage bill/total capital stock). For 1967 this represented a rate of return to capital slightly over 20 percent and an average wage of about $7,000. 1/ It is evident from the charts that the observed measures are not in equilibrium. Since the data used are from standard sources and are used in most studies of trade and industrial performance, why is the scatter of points so far from the theoretical equilibrium situation?

There are two possibilities. First, the data may be incorrect; second, the model might be inadequate because it does not account for the true equilibrium (or dis-equilibrium as the case may be). Something can be said about each of these aspects.

The possibilities for data error are considerable. Capital stock estimates are not known for their reliability; indeed, the method of valuation is questionable if asset values are a strong function of returns earned. Capital here includes total values of fixed assets, estimates of rented assets, and average inventory stocks held. These data items do not originate from the same source as the labor data (number of total employees); hence there might be a category matching

1/ Only a uniform depreciation figure has been subtracted. Ten percent of fixed assets was subtracted from value-added. The intercept rates of return to capital and labor were in effect sector size weighted averages for the manufacturing sector.

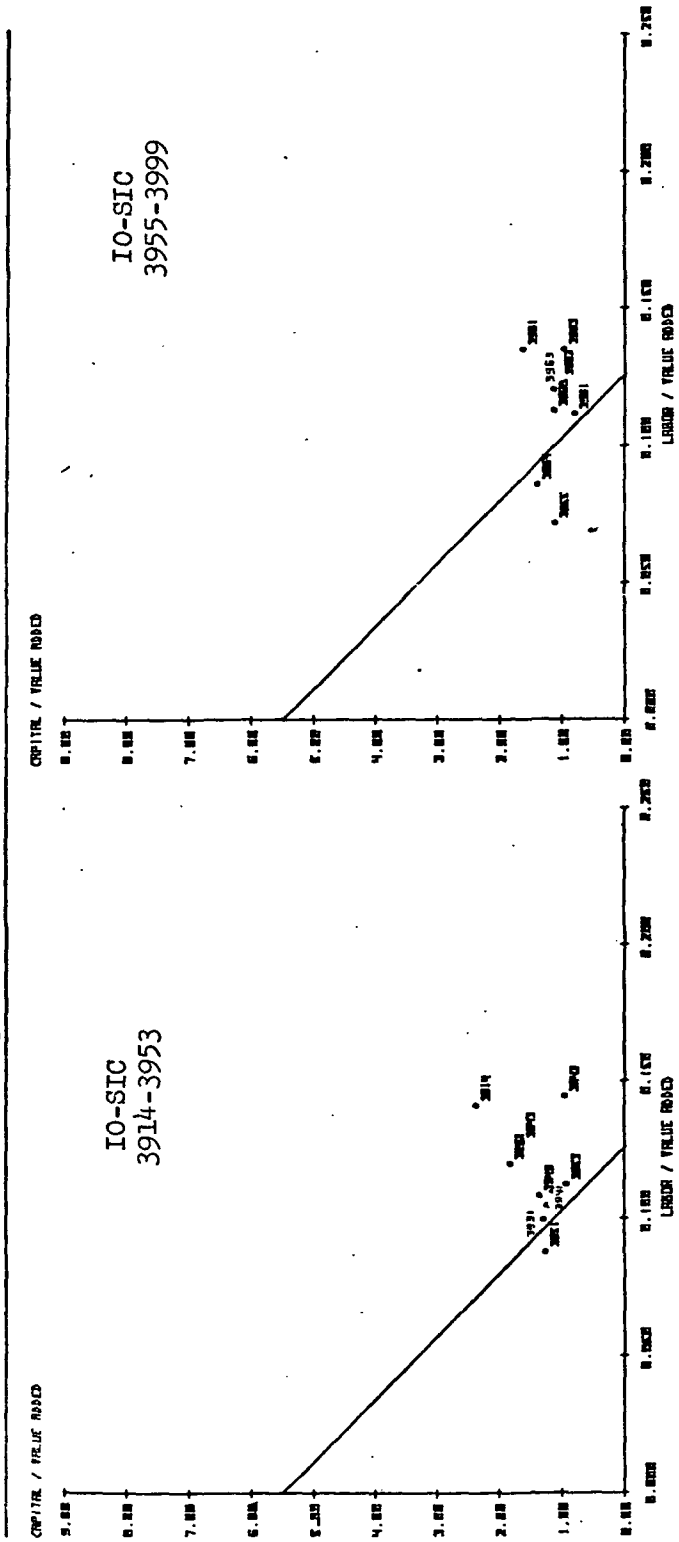
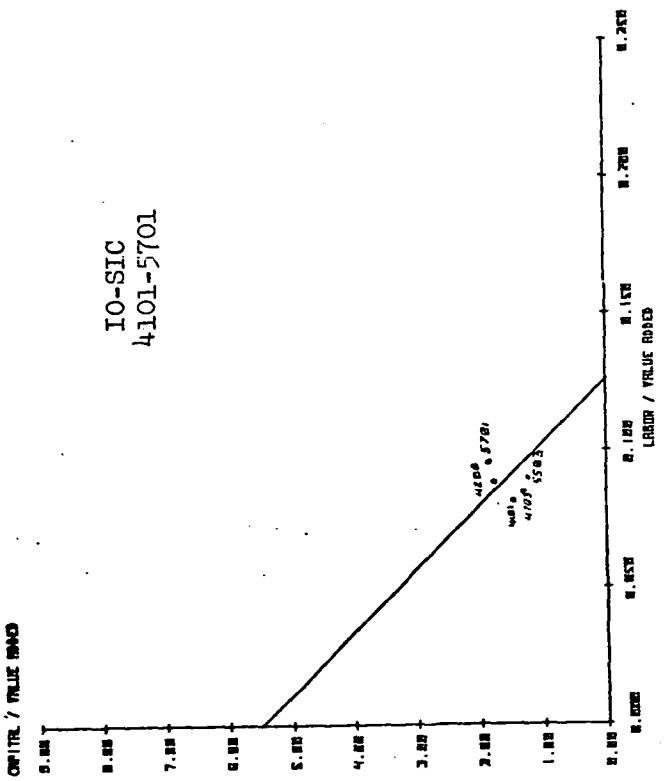
CARFT 6: Observed 1970 capital and labor requirements per dollar of value-added--Continued





problem. Value-added was calculated using an adjusted input-output definition and may therefore contain errors found in the input-output table values. Value-added, as calculated for the input-output table, is a residual and it carries and accumulates errors entering elsewhere. 1/ Tax data were used to remove direct taxes from value-added, but this originally was more aggregated than the IO-SIC level. For all of these reasons, it may be incorrect to apply such data to the type of static model used here. These data are normally used for time series analysis where changes in values over time are used and absolute value errors are not important.

On the other hand, the model might be inadequate. It may not be sufficiently detailed to reveal a correct portrayal of the extisting equilibrium. For example, labor could be divided to show different labor markets. A seemingly inefficient industry by the criteria in Charts 5 and 6 might be earning a sufficient rate of return to capital if the industry is located in a low wage region. Conversely, an industry which seems to be doing much better than average may be only earning an average return on its capital because union power may bring higher than average wages. Thus, the model as specified makes no assumptions about industrial structure or labor markets that might account for part of the scatter.

Next, there is the question of equilibrium itself. Some industries are growing due to an expanding demand, others are declining,

---

1/ See Walderhoug, op. cit.

perhaps because of declining demand or because they cannot compete with imports. Furthermore, profits fluctuate considerably and with different patterns in various industries during the business cycle.

Finally, there is the question of the relative movements of comparative efficiency measures, given price movements. A simple illustration will show that a given price change can cause a much larger CE change. Suppose a particular industry experiences a 20 percent price increase in its output products. Applying a 20 percent price increase to a value-added calculation can typically lead to a 50 percent increase in value-added. This in turn causes the capital per unit value-added and labor per unit value-added figures to decrease by one-third. Hence, in Figure 1, a point on the equilibrium line in an industry experiencing a 20 percent price increase would move inward by a full third of the distance to the origin. 1/

The effective tariff rate theoretically is a meaure of static comparative advantage if an equilibrium exists in the factor markets (all industries would lie in the straight line in Figure 1 in the protected situation). However, if some industries are doing much better relative to others, then similar effective rates would have to be given different considerations for different industries. For example, if an industry such as "s" in Figure 1 had a 20 percent ET rate, removal of all protection might simply move its CE measure out near the average efficiency line. On the other hand, the removal of a 20 percent ET rate from industry "t" would probably deal a severe blow, since that industry is not very competitive with existing protection. This

1/ It can be shown that if the base price structure for a sector changes, the effective rate will also change because value added may have changed.

implies that industries' general competitive health must be strongly considered when using effective tariff rate changes to measure the possible price import effects of tariff cuts.

The comparative efficiency measures, theoretically and empirically, do not serve well as total explanations of sector trade performance. The prices included in value-added are determined both by domestic and foreign demand and domestic and foreign supply. For most U.S. industries in the past, the domestic aspect has outweighed the foreign. Every U.S. industry, to survive in the long run, must compete relatively well with all other sectors for capital and labor resources, and its relative value-added price must roughly reflect that fact. A particular industry may, for example, have substantial exports because of products characterized by high technology; however, on a comparative efficiency basis it may be no better off than another U.S. industry which produces low-technology products. In other words, product or industry characteristics reflecting trade patterns may not be fully reflected in comparative (static) efficiency measures because many other factors also influence the latter. Therefore, even if comparative efficiency measures were to be considered in conjunction with effective tariff rates in judging adverse effects of tariff reductions, these efficiency measures should not be fully relied on as explanations of trade performance.

Empirical Work

Various types of regressions were run to examine aspects of the model described above as well as general aspects of sectors' trade

performance. The most difficult problem in this type of cross-section analysis seems to be multicollinearity, i.e., the situation where many of the explanatory variables are related to each other. This situation means that regression analysis cannot distinguish which of the related variables is the true explanatory one. There are essentially two methods around this problem. One is the use of factor analysis, principal components analysis, or some theoretical device to combine many related variables into a single variable. 1/ The other way out of multicollinearity is simply to select a set of roughly orthogonal variables for regression. Where one variable used is related to others that are discarded, one can assume that the chosen variable adequately represents the phenomena described by all of the related variables. The shortcoming in this or any other technique (such as factor analysis) is that some explanatory variables may be related even though there is no known theoretical reason for the relationship and in that event one may discard a variable which has some explanatory power.

Table 14 presents some evidence on the scatter pattern in Charts 5 and 6. The elasticity equivalents summarize the results. Some of the scatter is explained by differing wages in industries and some by differing total demand growth rates. While the percent of total variance explained is very small for the entire sample (7-8 percent), if 40 of the 246 observations are deleted, the R^2 rises to 23-27 percent.

1/ See An Industry Characteristics Analysis of the Competitiveness of U.S. Industries, U.S. International Trade Commission, a study that uses factor analysis to combine various industry characteristics into an orthogonal set of explanatory variables. These new "combined" variables then can be used in regression analysis.

Table 14.--Regression equations on factor comparative efficiency measures--Continued

Definition of the variables

FP267, FP270	-	1967 and 1970 comparative efficiency measures for each sector. These are value-added per total factor at average (weighted by size) factor price ratios.
WPH67, WPH70	-	1967 and 1970 average hourly wages in each sector.
GRTC	-	percentage growth of real domestic and foreign consumption for each sector from 1965 to 1970. It is calculated as the growth of production and imports minus the growth of the price deflator for each sector.

Source: Calculated from a databank at the International Trade Commission.

Note.--The point elasticity equivalents of the regression coefficients are as follows (calculated at sample means):

	WPH	GRTC
1967	0.54	0.060
1970	0.48	0.078

The equations omitting about forty observations produce a considerably better fit. Multicollinearity is not a problem for the variables shown. These equations are the second and fourth in the Table. (The ones stating observations were weighted by WT.)

Envisioning data problems, this is reasonably satisfactory for a typical cross-section analysis. One concludes that some of the scatter is explained by differing sector growth rates and by differing wage rates. The latter may be regional wage differences and/or union bargaining power differences in industries. There is obviously much left to be explained by other factors and data problems. 1/

The scatter of points did not explain trade performance in any satisfactory manner. However, it might be worthwhile to pursue some theories which would link poor comparative efficiency performance to stiff import competition. The reasoning is that as imports compete more on a price basis with domestic production, domestic prices have to be kept low, value-added is kept low, and therefore comparative efficiency is low. Such industries would either lose resources (resulting in slow or negative growth) or switch out of production of import competing items.

Table 15 includes more variables in an explanation of total comparative factor cost per unit value-added in a two and three factor model (note that these are the reciprocal of the measures in Table 14). Here wages are included as average hourly wage rates. Demand growth is represented by the growth of value-added while the price effect is included as the growth of a value-added price index. The results are quite strong in spite of some small multicollinearity problems.

1/ Multicollinearity is not a problem for the two variables related, as can be seen from the low correlation coefficient between them.

Table 15.--Regression results for total factor costs for a two- and three-factor model--Continued

Dependent variables:

FP267MTA - total factor cost per unit value-added (after taxes) in 1967 in a two-factor model. The two factors in this model were capital and labor.

FP367MTA - total factor cost per unit value-added in 1967 for a three-factor model. The three factors were capital, production workers, and white collar or non-production employees.

Independent variables:

GVA6570 - Percentage growth in value-added from 1965 to 1970.

WPH67 - Average hourly wage in 1967.

RMC - 1970 import consumption ratio.

DEP - 1970 effective tariff rate (using unweighted nominal tariff averages).

GVP6570 - Growth of value-added price indices from 1965 to 1970.

CONCR467 - 1967 concentration ratio.

Note.--the elasticity equivalents of the regression coefficients at the sample means are given below:

	FP267MTA	FP367MTA
GVA 6570	-0.104	-0.100
WPH	-0.580	-0.563
RMC	0.041	0.034
DEP	0.010	0.010
GVP 6570	-0.028	-0.028

The means for the effective rate are unusually high because a few effective ratios in a few sectors are very large.

There is some small multicollinearity problem for a few of the variables. The worst is for CONCR467 and WPH 67. However, CONCR467 is not statistically significant in the first equation and is omitted in the second equation. The coefficients seem relatively stable.

Static resource costs to produce a dollar value-added in 1967 seem to be (a) greater in the industries experiencing slower growth in value-added (they can't compete, hence they are not expanding as fast as other industries); (b) greater in industries with lower hourly wages (this may mean low wage areas or poor wage-paying ability due to non-competitiveness); (c) greater in industries experiencing higher import penetration ratios; (d) greater in industries with high effective tariff protection rates; and (e) greater in industries experiencing a slow growth in value-added prices.

The signs of all of the coefficients are reasonable. Other attempts at regression analysis do not show that tariffs or tariff changes are strong determinants of U.S. price changes in general. The analysis so far indicates that while protection is not the moving price force in the U.S. economy, it is associated more with the less competitive industries. The next step is to look at industry characteristics explaining trade performance.

Trade Performance

A rank correlation matrix for various trade performance variables is shown in Table 16. Variables 2-8 are derived from U.S. data sources while variables 9-12 are U.S. trade data from U.N. sources. ET rates for 1965 and 1970 are given as variables 13 and 14. All of the trade variables are for 1970.

The concordance problems crop up again as one inspects the difference between variables when sourced from the U.S. and the U.N. The U.N. data went through the same concordance route as the GATT Tariff while the U.S. sourced data went the direct route to the IO-SIC. This is evidenced by rank correlation of only 0.6 between equivalent types of measures using U.S. and U.N. data (specifically the trade balance and trade ratio measures).

Measurement of trade performance, especially for an economy when trade is a small portion of GNP, is a difficult problem. Part of the problem is that goods in some sectors are generally traded more than goods produced in others. The trade distortions caused by tariffs and NTB's complicate the problems. The concordance problems of matching trade and production data make certain kinds of trade measures very difficult to quantify accurately.

Finally, most sectors show both imports and exports; therefore, one cannot usually characterize a sector as a total exporting or importing competing sector. Note that import/consumption and export/production ratios are weakly but positively correlated.

Table 16.--Rank Correlation matrix of trade performance measures by IO-SIC--Continued

Variable definitions: Variables 2-8 use data directly from U.S. sources. Variables 9-12 use U.S. and other data from United Nations sources. All of the data are for 1970.

TBUS	-	(U.S. exports-imports)/(exports + imports)
TRUS	-	U.S. exports/U.S. imports
RMC	-	Imports/ (Production + Imports-Exports)
REP	-	U.S. Exports/Production
RMCA, REPA	-	Imports/consumption and export/production ratios adjusted to a product basis. This is done by correcting production data from an establishment to a product basis by multiplying by the specialization ratio and dividing by the coverage ratio as defined in the Industry Profiles data book.
PCHM6570	-	Percentage change in imports from 1965 to 1970.

Note that the U.N. prefixed variables denote U.S. data from United Nations sources.

UNUSTB	-	Same as TBUS
UNUSTBWD	-	(U.S. exports-imports)/world exports
UNUSTR	-	Same as TRUS
XUSSXWD	-	U.S. exports/world exports
EP65W, EP70W	-	U.S. 1965 and 1970 effective tariff rates (Nominal tariffs are imports weighted). These rates are the ones given in columns 3 and 5 of Table 8.

Although theories exploring trade performance abound, data to verify or reject them at the product level are not available. Therefore, researchers generally try ot explain trade performance using production sector data. Because of the problems noted above, most explanations account for only 20 to 30 percent of the variation in trade measures.

It is notable that the ET rate correlates negatively with trade performance measures such as trade balances and U.S. export shares of world exports (evidence of the validity of the ET rate as a measure of comparative advantage). Effective protection rates tend to be low in those sectors having good trade performance.

One can observe that export performance measures such as export shares do not correlate with import penetration measures. Trade balance measures seem to catch, to some extent, both good export performance and import competition.

One might expect to find different explanations for export performance than for imports. There are many theories calling for several types of explanatory variables. Unfortunately, this study does not have all of the variables, hence it cannot test all the proposed theories. Furthermore, multicollinearity makes a simultaneous test impossible. The study presents only a few variables explaining trade performance. The number was kept low because of the multicollinearity problem.

Table 17 gives several regression equations of trade performance with four explanatory variables. Some trade performance measures are not explained very well by the variable while others offer better results. 1/

1/ In all cases the number of variables was restricted to a set exhibiting almost no multicollinearity. The R^2 could perhaps have been improved by trial and error addition of more orthogonal variables. It also could be improved significantly by deleting 40-50 of the worst residuals on grounds of data or concordance problems. Size ordered plots of the residuals seemed to indicate that heteroscedasticity was not a problem (though no tests were performed).

Table 17.--Regression results for trade performance measures

REGRESSION OF [illegible] FOR OBSERVATIONS 1 TO 239.

Table 17.--Regression results for trade performance measures--Cont'd.

Variable definitions: All variables are in log form, hence the coefficients can be read as elasticities.

Dependent variable: (Complete definitions are given in Table 16). These are all for 1970.

TBUS	-	U.S. trade balance
TRUS	-	Exports/imports
RMC	-	Ratio of imports to consumption
REP	-	Ratio of exports to production
UNUSTB	-	U.S. trade balance
UNUSTBWP	-	U.S. trade balance divided by world exports
UNUSTN	-	Exports/imports
XUSSXWD	-	U.S. exports as a source of world exports
KLR	-	U.S. capital per employee ratio for 1970
PROFESS	-	Professional capital per employee ratio for 1970.
GUEPUS	-	PKR U.S. effective tariff rates from GATT nominal tariff sources. This rate is from column 8 of Table 10.
EPNTBUS	-	U.S. nontariff barrier indices run through the effective tariff rate formula.

The most significant variables explaining export performance are the capital labor ratio and professionals as a percent of the labor force. The latter measure reflects technology and perhaps some concept of human capital.

U.S. exporting industries tend to have much higher percentages of professional employees than those that do not export very much. Also, U.S. export industries seem to be capital intensive by some measures. The NTB measure is not statistically significant, and the effective tariff measure is significant and positive only in the equation explaining the import consumption ratio. 1/

The import consumption ratio is the poorest performing equation, though the significance of the ET rate is consistent with the rank correlation evidence in Table 16.

Based on the variables used here, good export performance seems to be associated with professionals in the work force (or the technology and human capital factor associated with this variable). Also, by most trade performance measures, U.S. exports are in (physical) capital-intensive industries. Industries not competing well with imports tend to be more highly protected. They may also be more labor intensive and have less professionalization of the work force, though the evidence

---

1/ The ET measure does have the correct sign in the trade balance equation; however, it is not statistically significant at the 95 percent level.

presented is not strong. More work needs to be done on the import side.

Tariff Patterns

Regression equations in Table 18 give some evidence of the industry characteristics associated with nominal tariff patterns.

The tariff rates seem to be (a) inversely related to the average wage rate, (b) directly related to the degree of industrial concentration, and (c) inversely related to the share of transportation input to production. These variables are reasonable and consistent with other evidence in this study. High wage industries do not need protection, they are competitive. Low wage industries are not as competitive and have protection because of or in relation to their non-competitiveness. Industries with high transport costs in production may incur some of the costs because of the nature of the product. Goods costly to transport or needing costly inputs transported are not as likely to be traded, hence they need less protection. Finally, higher tariffs in more concentrated industries are consistent with the political clout that large companies and unions can wield, thus extracting higher tariffs. Attempts to use these variables to explain effective rate patterns were very weak statistically. This is also a reasonable result since the effective tariff concept was not available when U.S. tariffs were legislated. 1/

1/ This does not mean that the ET concept is not relevant. Desired nominal rates yield a set of ET rates which may be different enough from the nominal rates in absolute terms to yield a quite different linear correlation pattern.

Table 18.--Regression results for tariff levels--Continued

Variable definition--Dependent variables:

USTT7070	-	U.S. nominal tariff rate for 1970, 1970 import weights were used for aggregation. This rate appears in column 3 of Table 1.
USUT70	-	Same as above except that no weights were used for aggregation. This rate appears in column 3 of Table 3.
LUSWT, LUSUT	-	The above respective variables in log form.

Independent variables:

CONTR467	-	1967 concentration ratio, the percent of sales by the 4 largest companies.
WPH70	-	1970 average hourly wage.
TRPINP63	-	Percent of input purchases from the transportation sector in the 1963 input-output table.
LCONC, LWPH, LTRP	-	The above variables in log form.

Comparative Advantage

Table 19 gives lists of sectors' ranks by a definition of comparative advantage (for 1970). The measure is derived by first regressing the observed comparative efficiency measure on explanatory variables such as wages and real growth rates. Then the fitted values are taken on the true protected comparative efficiency measures. This is done in order to smooth out some of the extreme points observed in the data and to account for the observed disequilibrium in the factor markets. These fitted points are then deflated by the 1970 unweighted ET rate and an NTB deflator. 1/ The NTB deflator was run through the IO table to give an effective NTB index. This does not give much weight to NTB's but it does give some weight for most sectors where they occur and it gives a lot for a few sectors. 2/

The comparative advantage rankings in Table 19 try to incorporate, into one measure, a relative status quo of industries, the ET rate, and some indicator of NTB's. 3/ These rankings are intended for use in comparison with rankings of effective rates alone. They are consistent with the model and the evidence presented explaining the status quo of comparative efficiency measures. They should be better than simple ET rates because they try to account for the existing relative health of industries in the base on which the ET (and NTB) rate is applied. The

---

1/ The NTB index was inserted in a different manner for some variables; see the table explanation.

2/ Hence there is an assumption that the NTB index run through the IO table does measure the "height" of the restriction. Practically, to the extent that the assumption is false, the NTB deflator will be close to unity and then will not affect the results.

3/ This is a theoretical way around the multicollinearity problem.

reader must be cautioned that data problems may cause some sector rankings to be wrong; hence, other supplementary data should be used if possible when determining a final ranking of comparative advantage.

The rank correlation matrix shows that the derived CA measures do rank correlate with trade performance measures a bit better than do ET rates above.

THE UPPER RIGHT HALF OF THE MATRIX CONTAINS THE SPEARMAN RANK CORRELATION COEFFICIENTS. THE LOWER LEFT HALF CONTAINS THE "T" SIGNIFICANCE STATISTICS. THE NUMBER OF DEGREES OF FREEDOM IS 241

Table 19.--Comparative advantage measures, their ranks, and associated data--Continued

Definitions of the variables:

Comparative advantage measures were derived by taking estimated values of (value added/total factors) and deflating by the effective tariff rate. Two methods were used in an attempt to incorporate information on NTB's. Method A was to multiply the ET deflator times an effective NTB index. Method B was to calculate a predicted value of comparative efficiency which set the NTB independent variable equal to zero. CA measures were run for two- and three-factor models. The units are free trade dollars of value-added per dollar of factor (capital and labor).

CA2A	-	(Fitted value of FP270)/[1 + (EP70U/100)] X [1 + (EPNTBUS/100)] for a two-factor model (capital and labor).
CA3A	-	As above (using FP370) for a three-factor model (capital, non-production workers, and production workers).
CA2B	-	(Predicted value of FP270 setting EPNTBUS=0)/ [1 + (EP70U/100)] for a two-factor model.
CA3B	-	As above (using FP370) for a three-factor model.
RCA2A, RCA3A, RCA2B, RCA3B	-	Ranks of above (from low to high comparative advantage)
REP	-	Ratio of exports to production
RMC	-	Ratio of imports to consumption
UNUSTB	-	U.S. trade balance (exports-imports) over (exports + imports). (U.N. sourced data)
UNUSTBWD	-	U.S. trade balance divided by world trade (exports)

Table 19.--Comparative advantage measures, their ranks, and associated data--Continued.

XUSSXWD	-	U.S. exports as a share of world exports (U.N. sourced)
EP70U	-	1970 effective tariff rate using unweighted nominal tariff averages
EPNTBUS	-	NTB frequency indices run through the ET formula
FP270	-	Observed comparative efficiency for 1970 in a two-factor model. Labor is converted to capital units via sector size weighted averages of the rates of return to capital and the wage rate
FP370	-	Observed comparative efficiency measure for 1970 using a three-factor model. Calculated in the same manner as FP270
WPH70	-	Average 1970 wage
GVA6570	-	Growth of value-added from 1965 to 1970
GVP6570	-	Growth of the effective price index from 1965 to 1970. The effective price index was calculated by running sector price deflators through the ET formula.

Table 19.--Comparative advantage measures, their ranks, and associated data--Continued.

Various types of regressions follow the table of comparative advantage measures and their ranks.

The first two equations (A & B) are used to estimate the fitted and predictive values for the CA2A, CA2B, CA3A, and CA3B. The remaining regression equations are attempts to improve the explanatory fit of observed comparative efficiency measures by in effect removing certain observations from the original set of 243 industries (using a dummy weighting scheme).

The fit (in terms of R^2) does improve remarkably in many cases. (It might be productive to re-run the CA measures using data from these improved reduced sample equations.)

The first two additional equations (C & D) removed 31 of the worst resuduals from equations A & B. The R^2 doubled.

Equations E & F are the most interesting because they cover approximately the 97 largest sectors of the economy (as measured by value-added). Here the fit is remarkable. Furthermore, the ET rate is highly significant, indicating that for the large industries in the economy, the ET helps to more than maintain the existing comparative efficiency.

Equations G & H cover industries with import consumption ratios of above five percent.

Generally, the significant explanatory variables are growth rates and wages. However, for large industries, it appears that the ET rate may also be helping to boost comparative industry performance.

Table 19.--Comparative advantage measures, their ranks, and associated data--Continued.

There was a small amount of multicollinearity in the equations, a factor which must be considered when doing more refined explanatory work. However, since these equations were used for forecast or predicted values of the dependent variable (to smooth the CA measure), the multicollinearity problem was not considered serious.

A rank correlation matrix of the various measures presented appears at the end of the table.

NUMBER OF UNIQUE MASTER CODES IS 377

NUMBER OF UNIQUE PAIRS OF MASTER AND SUBCODES IS 3367

Source: Prepared by V. Roningen and S. Kontos at the U.S. Tariff Commission.

Note: The master code in the input-output related Standard Industrial Classification (IO-SIC) as defined in the 478 sector 1963 U.S. input-output table. The subcodes original to each IO-SIC are the pure 5-digit Standard International Trade Classification (SITC) numbers. Definition of the SITC can be found in: Commodity Indexes for the Standard International Trade Classification, Series M, No. 38, Vol. 1, United Nations 1963.

A star (*) before each subcode indicates that this particular subcode also appears after another master code. The following description of the preparation of the concordance will emphasize its tentative nature. It was done in such a manner as to mimimize the amount of manual work and maximize the reliance on computer operation in the various preparation stages.

First, modifications of a TSUSA-import based SIC were carried out. This consisted of assignments of IO-SIC numbers to TSUSA numbers. This assigned all IO-SIC numbers (for sectors associated with physical quantities of output) a tariff rate. Some TSUSA numbers were assigned to two or more IO-SIC numbers. The original header tape also had U.S. import-based SITC numbers for each TSUSA number. When pure SITC numbers were matched with U.S. import-based SITC numbers, it was possible to run the concordance from pure SITC to IO-SIC. Because of some of the shortcuts

in the TSUSA to IO-SIC and pure SITC to import-based-SITC concordances, the resulting pure SITC to IO-SIC concordance may have same SITC numbers assigned to inappropriate IO-SIC sectors. The concordanc is better for converting tariff data to IO-SIC than it is for converting trade data.

All of the concordances are modifications of the basic trade data-production data concordances in: U.S. Foreign Trade Statistics, Classifications and Cross-Classifications, 1970, U.S. Department of Commerce, Bureau of the Census, Wash., D.C., 20233, Feb. 1971

APPENDIX B

THE NUMBER OF UNIQUE MASTER CODES IS 377

THE NUMBER OF UNIQUE PAIRS OF MASTER AND SUBCODES IS 3367

Source: Prepared by V. Roningen.

Note: The master code in the IO-SIC. The subcodes are the 5-digit BTN numbers which relate on a one-to-one basis to pure SITC numbers. The 5-digit BTN numbers are found in: Nomenclature for the Classification of Goods in Customs Tariffs, Customs Co-operation Council, Fourth edition (1972), Brussels, Belgium.

This concordance is identical to the one in Appendix A relating SITC numbers to IO-SIC numbers since each 5-digit BTN number corresponds to a 5-digit pure SITC number on a one-to-one basis.

APPENDIX C

Methodology of Effective Tariff Rate Calculation in the Study

Two calculation techniques used in the study differ slightly from usual effective tariff (ET) types of calculations. The results of the calculation with and without these techniques do not differ very much as an overall basis, but do differ for some industries. The results presented in the study proper incorporate the techniques while tables in appendix D present ET calculations both with and without one of the techniques.

The first technique was one of trying to calculate a vector of tariffs for input purposes that differed from the output tariff vector. This was done because: An industry produces a mix of goods; some goods are sold to consumers while some may be sold mostly to other industries as input materials. The tariff average covering an industry's output should include all types of output. The nominal tariff averages presented in Parts I and II are of this type. However, the tariffs of input goods into an industry's production should really exclude products which are designated as final consumption products. 1/ Thus a tariff average covering final and intermediate output of an industry is not necessarily the same tariff average that should reflect that industry's tariff costs to other industries buying the intermediate product. Therefore, a second vector of tariff averages which excluded products specifically designated as final manufactures was calculated and was used for the input tariffs in the ET formula.

1/ If it were possible, it would be better to specifically designate the input products for each sector. However, it was not possible with the available data. Much sector expertise would be needed to make this type of a modification.

This calculation was made possible by the following State of Transformation Codes which appeared on a TSUSA-SIC concordance tape for each TSUSA number.

A= Agriculture - raw material
B= Agriculture - semiprocessed
C= Agriculture - manufactured
D= Agriculture - combination of raw material and/or semiprocessed and/or manufactured goods
E= Industry - raw material
F= Industry - semimanufactured
G= Industry - manufactured
H= Industry - combination of raw material and/or semiprocessed and/or manufactured goods
J= Fishing - fresh fish
K= Fishing - semiprocessed
L= Fishing - manufactured
X= Not susceptible to classification in any one of the above categories

Input tariff averages excluded C, G, and L designated TSUSA numbers. The Special Advisor for Trade Agreements at the U.S. International Trade Commission provided these designations and the tariff computer tapes.

The second calculation technique was concerned with the use of the 478 sector U.S. input-output table for 1963 to get input weights and the ratio of value-added to total output, all of which are needed in the ET formula. A computer tape of the IO table and an accompanying description were obtained from the Bureau of Economic Analysis, U.S. Department of Commerce. More description of the table details plus information on indirect taxes at the 80-sector IO level was found in: Albert J. Walderhaug, "The Composition of Value-Added in the 1963 Input-Output Study," Survey of Current Business, April 1973. Additional data on indirect tax collection, especially for the liquor and tobacco

industries, was used to get approximations of indirect tax rates for most 1963 IO sectors.

All of the above data were used in conjunction with adjustment techniques to prepare a final adjusted vision of the IO table for use in ET formula .1.

First, only "direct allocations" and "domestic margin transactions" were used to define the input-output structure. This avoids the use of the item in the transaction table called "transfers." These are industries whose secondary products are treated as if sold to the industries where they would be primary. The use of these transfers would lead to double counting in the output structure. Transferred inputs would be counted as a purchase both from the industry where the product is actually produced as a secondary product and as an input from the primary industry where it is transferred. 1/ A better theoretical procedure might have been to include the transfer in the primary industry and subtract it from the industry for which the product was secondary; however the information was not available for this procedure.

Next, indirect taxes were netted out both from value-added and from purchased inputs. The philosophy represented here is that in the long run, indirect taxes are paid by the final consumer. Resources in any sector receiving lower returns because of indirect tax burdens should move to more lucrative production activities. The resultant 1963 IO-based output value (inputs + value-added) figures arrived

1/ The omission of transfers was suggested by J. Ozello of the U.S. State Department.

at in the above manner correlated the best with the 1963 shipments figures from the Census of Manufactures. The latter were found in Industry Profiles, 1970, Bureau of the Census, Department of Commerce. The Industry Profile shipments figures do not include "transfers" and exclude indirect taxes; hence they were a useful check on the above adjustment procedures.

Preliminary estimates of ET rates showed some sector rates to be highly unstable, i.e., they would change from being large and positive to being large and negative. This occurs when free trade value-added in the ET formula approaches zero and becomes negative. This problem may reflect reality (which would be an industry that could not even pay materials input costs if protection were removed) or it may reflect an overly small value-added share of total output value for the sector in the IO table. The latter was observed to be the case for some of the troublesome industries. Attempts were also made, using other data as checks, to determine whether the IO data were credible. Finally, the following adjustment procedure was adopted. Price deflators for 1963, 1965, and 1967 were prepared for all IO-SIC sectors. Most of the manufacturing deflators were aggregated from a tape of such data supplied by the Federal Reserve Board. Broad price deflators were added covering agriculture, mining, and construction. In many of the non-manufacturing sectors, the same deflator was used. The result was a crude vector of price deflators covering all IO production sectors for the named years. These were then run through the ET calculation. The output for each year was a vector of "value-added price deflators."

These were checked for erratic behavior. The argument used was that if the IO table presumably describes reality, then real price deflators run through the table should also reflect a realistic situation as far as the price incentives in resource movement are concerned. Here again, however, certain sectors (mostly the same ones giving trouble with tariff rates) exhibited erratic behavior. It was then decided to use this price information to adjust the value-added figures of the IO table in such a way as to stabilize the price behavior of the IO table over the three years. The following method was used to calculate the adjustment coefficient for value-added for each sector in the IO table.

A change in value-added price results in a new coefficient for value-added per unit output. The problem is to find an adjustment coefficient for the new value-added coefficient that implies a "reasonable" or desired change in value-added price when a vector of sector prices is run through the IO table. Let:

V = old value-added coefficient

$\tilde{V}$ = observed percentage change in value-added price

$\tilde{V}_D$ = desired percentage change in value-added price that would yield new adjusted value-added coefficient

V'_A = the new adjusted value-added coefficient

V' = the new unadjusted coefficient

$V'_A \equiv V'(1+A)$ where A is the desired adjustment coefficient

$V' \equiv V(1 + \tilde{V})$ and $V'_A = V(1 + \tilde{V}_D)$

$$\text{therefore } V'(1 + A) = V(1 + \tilde{V}_D)$$

$$\text{and} \quad V(1 + \tilde{V})(1 + A) \equiv V(1 + \tilde{V}_D)$$

$$1 + A = \frac{1 + \tilde{V}_D}{1 + \tilde{V}}$$

$$A = \frac{1 + \tilde{V}_D - 1 - \tilde{V}}{1 + \tilde{V}} = \frac{\tilde{V}_D - V}{1 + \tilde{V}}$$

Thus, an adjustment coefficient for value-added per unit output for each industry could be obtained by calculating a percentage change in value-added price $\tilde{V}$, selecting a desired or target change ($\tilde{V}_D$), and inserting these values into the formula for A.

Two versions of A were calculated. They were then normalized; i.e., the sector size weighted mean was subtracted from the coefficient for each sector. Finally, 3/4 of the sum of the normalized coefficient was used to adjust value-added input up or down for each sector in the 1963 input-output table.

The Federal Reserve deflators for 1963, 1965, and 1967 were run through the IO table using formula 1 in the text. This gave percentage changes in "value-added" prices for the IO sectors from a base year of 1958 = 100. 1/

The two adjustment coefficients required a theoretical target ($\tilde{V}_D$) percentage value-added price change. One target was to assume that given the maximum absolute change in the calculated $\tilde{V}$'s (from 1958 to 1967), the adjustment would be such that the target change ($\tilde{V}_D$)

1/ Here again, the problem of input versus output indices arises in the same manner as in the calculation of ET rates.

would not exceed the overall sector size weighted average maximum change. This restriction said in effect that value-added price changes in any sector should not realistically change too much from the average maximum change. The effect of this coefficient was to dampen down some of the enormous changes for a few sectors.

The second adjustment was done by assuming that the maximum value-added price change should not exceed the maximum absolute price change. This adjustment said that maximum changes in value-added prices should not greatly exceed maximum changes in sector prices for each sector. 1/

The rationale for both of these restrictions is that an unreasonable degree of disequilibrium between factor returns in various sectors is not credible. In the first case, if a sector's value-added price change deviates too much from the average, resources would flow into or out of the sector. In the second case, sectors that are super-sensitive to output price changes as far as returns to factors are concerned are suspect. Thus, one adjustment dampens value-added price changes on a cross-section comparison basis while the other does it on a within-sector price to value-added price change comparison. Expediency led to a final coefficient of 0.75 of the sum of the two types of adjustments. This seemed to catch the worst of the outlying ET rates.

The final adjustment coefficient simply changed the protected value-added coefficient. Input coefficients used in ET calculation were not changed.

1/ In these adjustments maximum absolute changes were the difference between the absolute value of the maximum and minimum indices. If I is an index and DX is the maximum absolute change:

$$DX = \text{Absolute value}\,(\text{maximum}\,(I_1, I_2, I_3)) - \text{Absolute value}\,(\text{minimum}\,(I_1, I_2, I_3))$$

Comparison of ET rates using completely unadjusted and adjusted IO coefficients showed that the ET rates for most sectors were almost identical. Only the erratic sectors were damped, and in most of the cases the previously erratic ET rates now settled down to positive high values.

A list of IO-SIC sectors and their unadjusted and adjusted ET rates follows for those sectors where the ET rate changed more than 10 percentage points.

PKR ET rates changing more than 10 percentage points in the adjustment procedure.

For the sectors in the list, those adjusted ET rates which move from very high rates to slightly higher or lower ones are credible, since their movement will not greatly affect sector rankings of ET rates. However, a more complete adjustment procedure could be made by using other data (such as capital and labor data) in the context of a model that crudely forced certain equilibrium conditions to be true. A simple model such as that presented in Part III might be useful for this purpose. The only other adjustment procedure would be the generous application of sector expertise.

APPENDIX D

Calculation of U.S. effective tariff rates with and without separate input tariff vectors.

Tables D-1 and D-2 show separate sets of nominal tariff averages for output tariffs and input tariffs. Table D-1 shows data using import weighted nominal tariffs while table D-2 uses unweighted nominal tariff averages. The rates in both tables are for 1965, 1970, and PKR rates.

The nominal output rates (NO) appearing in columns 2, 6, and 10 are the averages covering all of the TSUSA AVE's in each IO-SIC sector. These are the same averages that appear in tables 1, 3, 8, and 10.

The nominal input (NI) rates in columns 3, 7, and 11 are the input tariff vectors used in the ET calculations in tables 8 and 10 and in the ET calculations in columns 5, 9, and 13 of the tables in this appendix. Thus the ET rates (labelled EI in the appendix) are the same as those in tables 8 and 10 (calculated from TSUSA-sourced data). The input tariff vectors were calculated in the manner described in appendix C. Basically, they exclude TSUSA items that were designated only as final manufactures.

Columns 4, 8, and 12 of the tables in this appendix give alternative ET calculations which do not use the input tariff vector. Instead, the ET rates (column labelled EO) simply use the NO tariff vector to represent both the output and input tariff averages in the ET formula.

The appendix tables also include ET rates for those IO table sectors which do not produce goods competitive with imports. These are mostly construction and service sectors; their nominal tariff averages are set at zero; however, they do have ET rates since they purchase material inputs from sectors which are covered by tariffs. Their ET rates are negative, roughly indicating how much tariff protection elsewhere raises their production costs. The main point of including these sectors is to re-emphasize the complexity of protection effects when one uses the effective tariff concept.

The output (NO) and input (NI) nominal tariffs are highly correlated as indicated by rank correlation coefficients of about 0.95 or better between them. (See the rank correlation matrix at the end of each table in this appendix.) The ET rates calculated with (EI) and without (EO) the use of the separate input tariff sectors are also highly correlated. Their rank correlation coefficients hover around 0.99. Thus while there are some differences for specific sectors, and while there is some small overall difference between output and input tariff sectors as they were calculated, there is very little difference on a rank basis in the ET rates calculated with and without the separate input tariff vectors. (This lack of difference may simply mean that the input tariff vector calculated was not adequate.)

Table D-2.--U.S. effective tariffs using import weighted nominal tariff averages

Source: Prepared by V. Roningen at the U.S. International Trade Commission. The concordance is a modification of the ones on computer header tapes at the Commission. Some TSUSA numbers were assigned to two or more IO-SIC numbers in order that each IO-SIC sector producing traded goods would be covered by the tariff schedule.

APPENDIX F

VARIABLES USED IN THE ANALYSIS IN PART III

General Data Sources

1. Industry shipments, wages, employment, etc.--U.S. Dept. of Commerce, Bureau of the Census, Annual Survey of Manufactures, 1970, Industry Profiles, Washington, D. C., issued 1973.

2. Industry capital data--

   Book value of fixed assets and rental payments from U.S. Dept of Commerce, Bureau of the Census, Annual Survey of Manufactures, 1970, Book Value of Fixed Assets and Rental Payment for Buildings and Equipment, issued August 1973; other income from U.S. Dept. of the Treasury, IRS, Statistics of Income, 1970, Corporation Income Tax Returns, 1970; the formula for deriving the ratio of rented assets to owned assets was from George J. Stigler, Capital and Rates of Return in Manufacturing Industries, National Bureau of Economic Research, Priceton University Press, Princeton, New Jersey, 1963.

   Total capital stock (for 1967 and 1970) was found by adding the value of rented assets and average inventories (from 1) to the book value of fixed assets. The ratio of rented assets to owned assets was derived by dividing rentals paid by (depreciation plus net income before taxes and interest paid).

3. Direct tax data--

   U.S. Dept. of Treasury, IRS, Statistics of Income, 1970, Corporation Income Tax Returns, Washington, D.C., 1970.

   A ratio of taxes to income was calculated and used to deduct direct taxes from value-added.

4. Input-output data--

   1963 input-output tape for 478 production sectors and accompanying documentation, from the Bureau of Economic Analysis, U.S. Dept. of Commerce, Washington, D.C.

5. Indirect tax data and explanatory details concerning the 1963 IO study--

   Albert J. Walderhoug, "The Composition of Value-Added in the 1963 Input-Output Study", Survey of Current Business, April 1973.

6. U.S. import data and nominal tariff data--

   U.S. International Trade Commission computer tapes.

7. U.S. sourced export data--

   Dept. of Commerce, the computer tapes of U.S. exports.

8. U.N., U.S., and world trade data--

   World trade estimates for 1970 are from the United Nations. Other data came from U.N. tapes of trade data and from U.N. publications of trade data by the SITC code.

9. Non-tariff barrier indices and GATT sourced tariff rates--

   A databank for the study, Trade Barriers Report to the Committee on Finance of the United States Senate, Parts I, II, III, and IV, U.S. Tariff Commission, Washington, D.C., April 1974.

10. Effective tariff rates--

    Calculated at the U.S. International Trade Commission.

11. Professionals in the work force--

    U.S. Dept. of Commerce, Bureau of the Census, Census Population, Subject Report PC(2)-TC, Occupation by Industry, Washington, D.C., 1972

12. Industry price inflation--

Federal Reserve Board computer tapes plus some data compiled at the U.S. International Trade Commission.

About 300 variables were maintained in databank ordered by IO-SIC. Many of the variables were slightly different versions of the same measure. A more complete description of data sources can be found in an appendix to the Commission's study, "An Industry Characteristics Analysis of the Competitiveness of U.S. Industries." The bulk of that study worked with a databank of variables ordered by the TC-SIC described in Part I. However, the sources of data were the same for both the TC and IO-SIC databanks. Programs automatically aggregated data down to both levels where possible.

All statistical routines were run with programs that pulled clean data matrices from the databanks and inserted them directly into the statistical programs.
