EXHIBIT NO. 74.5 PRESENTED BY M. Kennecly

DATE 3/22/2= Kubota, Ltd.

3, 3-Chome, Nihonbashi-Muromachi Chuo-ku, Tokyo, Japan

Kubota, Ltd. 606 South Olive Street Suite 720 Los Angeles, California 90014

March 21, 1972

Mr. Kenneth Mason Secretary Tariff Commission Eighth & E Streets, N.W. Washington, D.C. 20436

Dear Mr. Secretary:

The purpose of this letter is to inform you of changes in Kubota, Ltd.'s production facilities which, in our opinion, are relevant to the Tariff Commission's pending investigation of asbestos-cement pipe from Japan under the Antidumping Act of 1921.

Last summer, Kubota, Ltd. reduced its capacity for making asbestos-cement pipe from 6,500 metric tons per month to 4,000 metric tons per month. This was accomplished by removing machinery for making asbestos-cement pipe and substituting machinery for extruding asbestos-cement structurals.

As a result of this reduction in our capacity to make a asbestos-cement pipe, we now plan in 1972 to establish our levels of export to the United States, Canada, Guam and other areas at 1,000 metric tons per month. Of this, 200 metric tons per month, we expect, will be sold to other areas than the U.S.A. The remaining 800 metric tons per month of capacity will be sold to the United States. The remaining 3,000 metric tons per month of capacity will be sold in Japan.

It should be noted that we are producing not more than 1,000 metric tons per month that meet American Waterworks Association's and American Society for Testing Materials! specifications.

Yours very truly,

KUBOTA, LTD.

Manager Kubota, Ltd.

WATER UTILITIES' USE OF PLASTIC PIPE

Los Angeles, Calif., has been experimenting with plastic pipe installations for more than sixteen years. Two compositions have been given field trials, and a third is undergoing "proving-ground" tests. Results, so far, are encouraging. Skagit County, Wash., another of the districts in the US to pioneer the use of plastic pipe, reports favorably about the installation of various types and sizes of pipe and tubing used in its distribution system.

Los Angeles County-J. M. Wool

TO DATE the installation of plastic piping by the Los Angeles Dept. of Water and Power has been on a trial basis only. Three different plastic materials are being evaluated at the present time: both polyvinyl chloride (PVC) Type 2 and polyethylene 3306 have been installed in services; polybutylene (PB) is being tried in lines on department property (see Table 1).

Polyvinyl Chloride

The first PVC installations were made in Sep. 1954, and, through Jun. 1959, 315 services were installed using PVC in 1-in-tubing size with wall thicknesses of 0.100 in and approximately 0.070 in. Water pressures ranged up to 167 psi. Of the total number of installations, 246 are still in service, 28 failed due to various causes (see Table 2), and 41 were replaced or no longer exist for reasons other than material failures.

Two failures were attributed to hot water backing up in the lines and softening the plastic, and two leaks developed in flared compression joints at the main-line cock as a result of improper bedding and back-filling methods, which caused excessive settlement of the back-fill material. The remaining failures were attributed to two primary causes.

The first cause was generally unsatisfactory installation. Many early installations made use of heat flaring in the field to make the compression reconnections at the main-line cock and at the curb valve. Also numerous riser bends at the meter were made by heating the tubing. Improved joining techniques and fittings now make it unnecessary to attempt to flare, bend, or join PVC in the field by the use of heat.

The second cause of many leaks was the excessive dimensional difference between the inside diameter of socket fittings and the outside diameter of the spigot portion of solvent-fused joints.

Closer manufacturing tolerances are now specified—and held—so that difficulties due to excessively loose fits for solvent-fused joints have been climinated, for the most part.

An up-to-date evaluation of service involving PVC lines shows the following:

- 1. The material has proved to be durable and trouble free.
- 2. Field installation crews had not been pleased with the material from an installation standpoint; however, most of their early complaints have been voided by new and better joint fittings and new installation methods.
- 3. In 1956 an overall comparison of initial costs made between 49 1-in. PVC-tubing service installations and 49 copper-tubing services of the same size showed copper to be the more economical of the two materials.

Polyethylene

In Jul. and Aug. 1966, 21 services were installed using 1-in. PE 3306 piping with a standard dimension ratio of 7 (SDR-7) and a pressure rating of 160 psi. These services were all made with compression-type connections in which pipe flaring was involved. Regular copper-tubing-size compression fittings were used except that the tailpieces were oversized to accommodate the larger outside diameter of the PE pipe. The flaring operation involved mild heat application to the ends to be flared. No trouble was experienced in making the riser bends cold. Pressures ranged up to 122 psi. To date no failure of any type has taken place; however, two lines were inadvertently torn out during street excavations.

An evaluation at this time of these installations and the PE 3306 pipe shows the following:

1. The installations have been trouble free.

2. Field-installation crews reported that they liked working with the material and had no complaints about installation techniques.

3. A complete comparison of the total installation costs per service was made for the 1-in. PE 3306 piping and 1-in. copper tubing installed in the same subdivision. Copper proved to be slightly less costly.

Polybutylene

To date testing of PB consists of an installation of I-in. PB 2110 tubing with a pressure rating of 160 psi. Lengths of this material were installed on Department property in Feb. 1969. Water pressures involved have been 160 psi and approximately 200 psi. One loop is exposed to sunshine and atmosphere, and other lines are underground near the edge of an orange grove where gophers are present. Connections are all by standard coppertubing compression fittings that require flaring. All flares were made cold. No leaks or troubles have occurred to

Future Studies and Evaluations

At the present time it appears that the total initial cost (materials plus labor) of plastic service installations is less than the cost of comparable copper installations. Any significant changes in the physical characteristics of the installed plastic materials that might develop over prolonged periods, such as 40 or 50 years, remain a major concern of the Department, however.

The Los Angeles Dept. of Water and Power plans to add new trial installations of plastic-piping materials along with their required fittings and to keep abreast of developments in the field of plastic materials for water-system use.

thate discussion at the Annual Conference on Jun, 22, 1970, by J. M. Wool (Active Member, AWWA), Sr. Water Works Engr., Dept. of Water and Power, Los Angeles, Calif., and Robert A. Yale (Active Member, AWWA). Sr. Engr., Public Utility District No. 1, Skagit County, Wash. [D]

Before plastic pipe can be installed, it must be . . .

Skagit County-Robert A. Yale

PUBLIC Utility District (PUD) No. 1 of Skagit County, Wash., has been working with plastic-pipe material for over seventeen years and today counts 110 mi of plastic tubing and pipe in its broad area of service.

Skagit County PUD operates a unique water system that encompasses three small cities, two towns, and the large productive farm areas surrounding these centers. Today a total of 260 mi of pipe plant is serving 9,100 water customers, 42 per cent of whom are located outside the limits of the three cities. The distribution plant extends into 100 sq mi, of Skagit Valley. Most of the District's system is completely tied together with transmission and distribution lines delivering water from the main sources of supply.

Virtually all of the rural plant has been constructed since 1940; in that

11

[®] Removals due to new main installations, destruction by new extravations, and relocations in conjunction with construction projects. same period over 90 per cent of the city systems have been built, by additions and replacements. Even pipe plant installed in the early '40s from materials then available—such as wood stave and thin-wall steel pipe—also has been replaced, or is being replaced today.

Waters in the area are very soft and usually contain some amounts of dissolved iron. Consequently, the water supplied is corrosive to steel and conducive to the development of iron bacteria tuberculation on steel- or ironwall pipe. Feasibility and economics have dictated the installation of small-diameter, least-cost pipe in the sprawling rural areas. The need has been for domestic water service. Fire-protection-pipe sizing has not been practical, except in and near the cities,

Polyethylene Tubing

Interest in plastic material developed because of poor results with conventional service piping. Galvanized-steel service pipe purchased after the early '40s plugged up with iron tubercules so badly that the district had to replace such pipes within ten years. Aggressive soil conditions often would corrode through such pipe in even less time. Copper has been a good material, but cost had steadily increased.

In 1952, six 4-in. water services using polyethylene (PE) tubing were installed and carefully watched. These services were easy to install, and they performed without failure. In 1953 several more services were installed.

The tubing was available in several pressure ratings, which were set largely by the manufacturer. Since the cost was so low in comparison with galvanized and copper pipe, the district chose to purchase tubing with a pressure rating of 125 psi—well over the water pressure in the mains. Installation locations were chosen in areas where normal pressures did not exceed 60 psi and where extensive paving improvements were unlikely.

Since corrosion to steel by aggresive soils was a primary concern, the District did specify stainless-steel clamps and stainless-steel screws to clamp the tobing around brass-insert fittings. (For a short time nylon fittings were used, but, after a year or two of service, these fittings would fail. The nylon would absorb moisture, lose its toughness; and become brittle. Eventually, every such nylon fitting installed had to be replaced with either a brass, copper, or molded-plastic fitting.)

Despite dire predictions that the tensile strength of the PE would fall with time, there have been fewer than a half-

. . . cleaned and solvent-cemented.

dozen failures in thousands of PE-tubing services installed since 1951—excepting those broken by earthwork contractors. Using a heavier tubing helped ensure this success; so did the use of brass fittings at points of external stress, such as coupling connections and ells.

Meanwhile, since PE pipe use was inaugurated, the creation of plastic formulations has been explosive. When polyethylene was first used, there were five basic types. Since that time, apparently, "hundreds" have been discovered. From these developments have come the formulations that are used today for making several different densities of tubing material for water service, none of which, for the chemist, even closely resemble that from which the first tubing was made.

The District's records show that over 200,000 ft of 3- and 1-in, PE tubing are now installed in over 6,500 of the District's water services. Since the adoption of the Commercial Standard for PE pipe in 1963, the District has been using medium-density tubing, designated PE 2306, in class 125 pressure rating. Accumulated experience provides no reason to use higher-rated tubing or to consider the new flare-type tubing that utilizes copper flare fittings. It frequently has been suggested that inserts reduce the capacity of the tubing because of the increased pressure loss

through the smaller inside diameter of the fitting. This condition has not been substantiated. Since the total length of reduced cross section is only about 4 in. in a service, the head loss in the fittings is negligible, and the more costly high-density flare tubing does not seem warranted.

Smaller Distribution Mains

The smooth interior wall of plastic pipe and evidence that plastic is immune to corrosion as water suppliers know it-thereby providing good longterm flow characteristics-led the District to try the material in small distribution mains. As mentioned before, galvanized steel had not performed well and some difficulty was experienced? with 2-in. asbestos-cement pipe. A hard-wall plastic pipe that had to be solvent-welded with molded couplings was introduced to the District. This pipe was made of acrilonitrile-butadiene-styrene (ABS) material. The material has a much higher tensile strength than polyethylene and, therefore, is less expensive than PE pipe in larger than 1-in: sizes for an equivalent pressure rating (since less raw material is required to make it)."

In 1953 the first 2-in. ABS pipe was laid. It had solvent-welded-pipe (SWP) dimensions; that is, it had a somewhat smaller outside diameter

than galvanized-steel pipe. It came in 20-ft lengths that were joined by cementing or solvent welding molded couplings of higher-density material over the pipe ends. Two cements were required: (1) a strong solvent to etch into the dense interior wall of the coupling; (2) a solvent with ABS material mixed in to act as a filler in the joint—this solvent being applied to the outer wall of the pipe end.

Shortly after beginning the installation of this material it was realized there would be some advantages in using iron-pipe-size outside-diameter pipe, so that certain standard repair bands and flexible couplings could be used when needed. The District's suppliers were able to furnish this size with no difficulty, and it has been the standard for many years now. However, there are a good many feet of old SWP dimension pipe in service that are run across occasionally.

The District had the good fortune to purchase its earliest ABS pipe from a reputable water-works supply house, which in turn obtained the pipe from a very conscientious extruder who was interested in the District's problems. A number of problems indeed were encountered in those early years, some of which the District solved on its own. Possibly pipe would be received that was damaged or scarred. Or perhaps it would be egg shaped so that assembly would be difficult. Possibly the interior wall would be rough, or dimensional tolerances such that it would not fit properly into couplings. The supplier and extruder always worked hard to correct these problems when they occurred. Looking back, it is apparent that the District pioneered the field in the '50s and early '60s. The District even developed its own design for a

After a while, higher-density ABS resins were developed, and it became possible to mold or extrude couplings of the same material as the pipe. Solvent welding was simplified, since only one solvent was then necessary.

From 1953 through mid-1964, the Skagit County PUD installed over 38 mi of ABS pipe in sizes from 14 in. through 4 in. Most of it is in the 2-in. size. Over 95 per cent of this material is still in service, including the very earliest pipe. Undoubtedly one major factor in the District's success up until now has been the conservative rating of the pipe purchased, Minimum-class 150-psi ABS pipe was used first, and it was raised to 160 psi when a stronger ABS material became available in the late fifties. success factor was that the installers were well trained and the same men always worked with the plastic installa-

However, not all installations were trouble free. At one time, a new ABS formulation, designated as HTHT (high tensile-high temperature), was offered. It was supposed to be superior to earlier types, and, since it was a stronger material, the pipe could be made with less wall thickness for the same pressure rating, thereby further reducing first cost.

It proved to be a terrible flop. Internal stresses were created in the pipe from improper tempering after extrusion. These stresses caused the pipe to split in most unexpected ways. Some pieces would split in storage. The District's two installations using this material never did hold water for more than a day or two. The embarrased pipe supplier covered all the expenses of replacing the pipe with the former ABS type pipe, but the experience did raise District concern since the splits in this pipe were the same as had been experienced on some occasions with the regular ABS.

The District has experienced failures in older ABS pipe installations in the past few years. Sections of pipe will split open longitudinally, sometimes the

full 20-ft length between couplings. Some have split when but barely disturbed—such as by shaking the ground during nearby escavation activity. In three cases the District installed pressure-reducing valves at the head of dead end lines, dropping the pressure from 80 psi, or more, to 50 psi. On these lines continued failures have ceased.

Servicemen have found that ABS pipe splits are only in the earliest types of pipe and that none of the class 160 pipe made with higher-strength material has failed, unless broken by impact.

Polyvinyl Chloride Pipe

In early 1964 the two prime extruders near the District's area, from which most of the pipe came, tooled up to manufacture pipe from polyvinyl chloride (PVC) plastic. It had been said that this material was superior to ABS for pressure pipe, and the District was anxious to try it. The standards as published by the US Dept. of Commerce effectively had standardized the manufacturing of plastic pipe, and the District was sold on the higher impact and tensile strengths of PVC. Before the year ended conversion had been completed from ABS to PVC pipe in the smallest-main installations.

In the past six years, the District has installed and placed into service just over 34 mi of PVC plastic pipe. The pipe has all been of the PVC 1120 or 1220 type, designed for 200 psi working pressure. Most of this pipe has been of the 2-in, and 3-in, size, though over 4 mi of 4 m. PVC pipe, also of class 200 psi working-pressure rating, has been installed in the past year.

PVC pipe is available to the District with (1) molded couplings for gluing to pipe ends; (2) pre-belled pipe ends for gluing sections together in a bell and spigot method, and (3) rubbergasketed bell ends molded or factory-glued on one end of each pipe length. The last joint is the most costly but requires no gluing or curing time. For inexperienced personnel it is suggested as the most positive joining method.

Considerable nuccess has been obtained with the r.e-belled pipe ends for gluing. Now all District pipe is ordered this way. It is very important, though, that the pipe maker know exactly what he is doing when

forming the belled end. The District will not accept deformed or imperfect bell ends.

The cost of class-200 PVC pipe has become very competitive with other types of pipe the District normally has used in 4-, 6-, and 8-in, sizes. The 4-in, PVC is used now, because it is found easier to install and the first cost is less. Because of the success with this size and the District's experience with plastics, it most likely will be using 6-in, PVC before 1971.* Actually there are a few hundred feet of 6- and 8-in, PVC in service now under highways and railroads within steel casing pipes.

PVC pipe has been received with damaged ends, poorly factory-installed couplings, or egg-shaped bell ends. Careful inspection before installation by experienced pipe installers has disclosed these blemishes before assembly. Today the suppliers seem to be more careful, although inspection of every piece continues. To this date the District has not experienced a single PVC-pipe failure after the pipe has been placed in full service.

Conclusion

The District has been very close to the evolution and refinement of plasticpipe manufacture for many years. Considerable savings have been realized with the use of plastics, even though some failures in ABS types are being experience today. These savings have accrued from first-cost-material savings and continued excellent-flow characteristics.

The success of plastic materials in Skagit County probably has been the result of having experienced installers, keeping close contact with the pipe manufacturers, and applying conservative pressure ratings. Although system pressures seldom exceed 100 psi, the District is still specifying class 200 pipe in PVC materials. The longer success with polyethylene tubing allows continued use of class 125 tubing, however.

The District looks forward to continued use of plastic pipe and tubing and the expansion of its experience in larger diameters.

*Since the submission of this paper, the District has installed 6,730 ft of 6-in. class 200 PVC pipe with success.
